

HC32F072 Series

32-bit ARM® Cortex®-M0+ Microcontroller

Reference Manual

Rev1.72 March 2025

Statement

- ★ Xiaohua Semiconductor Co., Ltd. (hereinafter referred to as "XHSC") reserves the right to change, correct, enhance, modify Xiaohua Semiconductor products and/or this document at any time without prior notice. Users can get the latest information before placing orders. XHSC products are sold in accordance with the terms and conditions of sale set forth in the Basic Contract for Purchase and Sales.
- ★ It is the customer's responsibility to select the appropriate XHSC product for your application and to design, validate and test your application to ensure that your application meets the appropriate standards and any safety, security or other requirements. The customer shall be solely responsible for this.
- ★ XHSC hereby acknowledges that no intellectual property license has been granted by express or implied means.
- ★ The resale of XHSC Products shall be invalidated by any warranty commitment of XHSC to such Products if its terms are different from those set forth herein.
- ★ Any graphics or words marked "®" or "™" are trademarks of XHSC. All other products or services shown on XHSC products are the property of their respective owners.
- ★ Information in this notification replaces and replaces information in previous versions.

Table of Contents

Statement	2
Table of Contents.....	3
Table Index.....	24
Figure Index.....	26
Overview.....	33
1 System Structure.....	34
1.1 Overview	34
1.2 System address division.....	35
1.3 Memory and Module Address Assignment.....	36
2 Operating mode.....	38
2.1 Operating mode	40
2.2 Sleep mode	41
2.3 Deep sleep mode	42
3 System Controller (SYSCTRL).....	45
3.1 System Clock Introduction.....	45
3.1.1 Internal high speed RC clock RCH	46
3.1.2 Internal low speed RC clock RCL	47
3.1.3 External low-speed crystal oscillator clock XTL.....	47
3.1.4 External high-speed crystal oscillator clock XTH	47
3.1.5 Phase-locked loop clock PLL	47
3.1.6 Internal high speed clock RCH48M	48
3.1.7 Clock start process	48
3.2 System Clock Switching	48
3.2.1 Standard Clock Switching Process	49
3.2.2 RCH switching process between different oscillation frequencies.....	49
3.2.3 XTL Example from Other Clocks.....	50
3.2.4 Switching from other clocks to XTH example.....	50
3.2.5 Switching from other clocks to RCL example	51
3.2.6 Switching from other clocks to RCH example	51
3.2.7 Example of switching between PLL and RCH, the reference clock is RCH	52
3.2.8 Example of switching between PLL and XTH, the reference clock is XTH	53
3.3 Clock Calibration Module	54
3.4 Interrupt Wakeup Control	55
3.4.1 Enable the NVIC corresponding to the module that needs to wake up the processor	
	56

3.4.2	Method not to execute interrupt service routine after wake-up from deep-sleep mode	56
3.4.3	Using exit hibernation feature	57
3.5	Register	58
3.5.1	System Control Register 0 (SYSCTRL0).....	59
3.5.2	System Control Register 1 (SYSCTRL1).....	60
3.5.3	System Control Register 2 (SYSCTRL2).....	61
3.5.4	RCH Control Register (RCH_CR)	62
3.5.5	XTH Control Register (XTH_CR).....	63
3.5.6	RCL Control Register (RCL_CR).....	64
3.5.7	XTL Control Register (XTL_CR)	65
3.5.8	PLL Control Register (PLL_CR).....	66
3.5.9	Peripheral Module Clock Control Register (PERI_CLKEN0).....	67
3.5.10	Peripheral Module Clock Control Register (PERI_CLKEN1).....	69
3.5.11	Timer Clock Multiplication Control (OVCK_CR)	70
3.5.12	RC48M Control Register (RC48M_CR).....	70
4	Reset Controller (RESET)	71
4.1	Reset Controller Introduction.....	71
4.1.1	Power-on and power-off reset POR.....	72
4.1.2	External reset pin reset.....	72
4.1.3	WDT reset	72
4.1.4	PCA reset	72
4.1.5	LVD low voltage reset	72
4.1.6	Cortex-M0+ SYSRESETREQ reset.....	72
4.1.7	Cortex-M0+ LOCKUP reset	72
4.2	Register	73
4.2.1	Reset flag register (RESET_FLAG)	73
4.2.2	Peripheral Module Reset Control Register (PERI_RESET0).....	74
4.2.3	Peripheral Module Reset Control Register (PERI_RESET1).....	76
5	Interrupt Controller (NVIC)	77
5.1	Overview	77
5.2	Interrupt priority	77
5.3	Interrupt digraph	78
5.4	Interrupt Input and Suspend Behavior.....	79
5.5	Interrupt wait.....	81
5.6	Interrupt source.....	81
5.7	Interrupt structure diagram.....	83
5.8	Register	85

5.8.1	Interrupt Enable Setting Register (NVIC_ISER).....	86
5.8.2	Interrupt Enable Clear Register (NVIC_ICER).....	86
5.8.3	Interrupt Pending Status Set Register (NVIC_ISPR)	87
5.8.4	Interrupt Pending Status Clear Register (NVIC_ICPR)	87
5.8.5	Interrupt Priority Register (NVIC_IPR0).....	88
5.8.6	Interrupt Priority Register (NVIC_IPR1).....	88
5.8.7	Interrupt Priority Register (NVIC_IPR2).....	89
5.8.8	Interrupt Priority Register (NVIC_IPR3).....	89
5.8.9	Interrupt Priority Register (NVIC_IPR4).....	90
5.8.10	Interrupt Priority Register (NVIC_IPR5).....	90
5.8.11	Interrupt Priority Register (NVIC_IPR6).....	91
5.8.12	Interrupt Priority Register (NVIC_IPR7).....	91
5.8.13	Interrupt Mask Special Register (PRIMASK).....	92
5.9	Basic operation of the software	93
5.9.1	External interrupt enable	93
5.9.2	NVIC interrupt enable and clear enable.....	93
5.9.3	NVIC interrupt pending and clear pending.....	93
5.9.4	NVIC interrupt priority.....	93
5.9.5	NVIC interrupt mask.....	94
6	Port Controller (GPIO)	95
6.1	Introduction to Port Controllers	95
6.2	Port Controller Main Features	95
6.3	Port Controller Functional Description	96
6.3.1	Port configuration function	96
6.3.2	Port write	98
6.3.3	port read.....	99
6.3.4	Port digital multiplexing function.....	100
6.3.5	Port interrupt function.....	102
6.4	Port configuration operation flow	103
6.4.1	Port multiplexing is configured as an analog port operation flow	103
6.4.2	Port multiplexing configured as a digital universal port operation flow	103
6.4.3	Port multiplexing configured as a digital function port operation flow.....	103
6.4.4	Port multiplexing is configured as a debug test port operation process	103
6.4.5	Port multiplexing configured as infrared output signal operation process	103
6.4.6	Port high level interrupt operation flow	103
6.4.7	Port low level interrupt operation flow.....	104
6.4.8	Port rising edge interrupt operation flow	104
6.4.9	Port falling edge interrupt operation flow	104

6.4.10	Port pull-up enable configuration operation flow	104
6.4.11	Port pull-down enable configuration operation flow.....	104
6.4.12	Port Enhancement Driver Configuration Operation Flow	104
6.4.13	Port open-drain output configuration operation flow	105
6.4.14	Port bit setting operation flow.....	105
6.4.15	Port bit clearing operation flow.....	105
6.4.16	Operation flow of port bit setting and clearing	105
6.5	Port Controller Register Description	106
6.5.1	Port general register.....	112
6.5.2	Port Auxiliary Register	121
6.5.3	Port PA Function Selection Register	127
6.5.4	Port PB Function selection register	135
6.5.5	PORT PC FUNCTION SELECT REGISTER	143
6.5.6	Port PD Function selection register	151
6.5.7	Port PE Function Selection Register	159
6.5.8	Port PF Function Selection Register.....	167
7	I2C bus (I2C).....	173
7.1	Introduction	173
7.2	Main characteristics	173
7.3	protocol description.....	173
7.3.1	Data transmission on the I2C bus.....	173
7.3.2	Acknowledgment on the I2C bus	175
7.3.3	Arbitration on the I2C bus.....	175
7.4	Functional description	177
7.4.1	Serial clock generator.....	178
7.4.2	Input filter	178
7.4.3	Address comparator.....	178
7.4.4	response flag	179
7.4.5	interrupt generator	179
7.4.6	Operating mode.....	179
7.4.7	Status code expression.....	184
7.5	Programming example	186
7.5.1	Master sending example.....	186
7.5.2	Master receive example.....	187
7.5.3	Slave receiving example.....	188
7.5.4	Slave sending example.....	188
7.6	Register description.....	190
7.6.1	I2C Baud Rate Counter Enable Register (I2Cx_TMRUN)	191

7.6.2	I2C Baud Rate Counter Configuration Register (I2Cx_TM)	191
7.6.3	I2C Configuration Register (I2Cx_CR).....	192
7.6.4	I2C Data Register (I2Cx_DATA).....	193
7.6.5	I2C Address Register (I2Cx_ADDR).....	193
7.6.6	I2C Status Register (I2Cx_STAT).....	194
8	Serial Peripheral Interface (SPI)	195
8.1	Introduction to SPI.....	195
8.2	Main Features of SPI	195
8.3	SPI Functional Description	196
8.3.1	SPI master mode.....	196
8.3.2	SPI slave mode	197
8.3.3	SPI data frame format.....	198
8.3.4	SPI Status Flags and Interrupts.....	200
8.3.5	SPI multi-machine system configuration instructions	200
8.3.6	SPI pin configuration description	202
8.4	SPI programming example	203
8.4.1	SPI master sending example	203
8.4.2	SPI master receive example	203
8.4.3	SPI slave sending example	204
8.4.4	SPI Slave Receive Example.....	205
8.5	SPI register description.....	206
8.5.1	SPI Configuration Register (SPIx_CR)	207
8.5.2	SPI Chip Select Configuration Register (SPIx_SSN)	208
8.5.3	SPI Status Register (SPIx_STAT)	209
8.5.4	SPI Data Register (SPIx_DATA)	210
8.5.5	SPI Configuration Register 2 (SPIx_CR2)	211
8.5.6	SPI Interrupt Clear Register 2 (SPIx_ICLR).....	212
9	Clock Trim Module (CLKTRIM)	213
9.1	Introduction to CLKTRIM	213
9.2	CLKTRIM main features.....	213
9.3	CLKTRIM function description	213
9.3.1	CLKTRIM calibration mode	213
9.3.2	CLKTRIM monitoring mode.....	216
9.4	CLKTRIM register description.....	219
9.4.1	Configuration Register (CLKTRIM_CR)	220
9.4.2	Reference counter initial value configuration register (CLKTRIM_REFCON).....	221
9.4.3	Reference Counter Value Register (CLKTRIM_REFCNT)	221
9.4.4	Calibration Counter Value Register (CLKTRIM_CALCNT)	222

9.4.5	Interrupt Flag Register (CLKTRIM_IFR).....	222
9.4.6	Interrupt flag clear register (CLKTRIM_ICLR)	223
9.4.7	Calibration Counter Overflow Value Configuration Register (CLKTRIM_CALCON) ...	223
10	Hardware divider module (HDIV)	224
10.1	Introduction to HDIV.....	224
10.2	HDIV main characteristics	224
10.3	HDIV function description.....	225
10.3.1	HDIV operation process	225
10.4	HDIV register description.....	226
10.4.1	Dividend register (HDIV_DIVIDEND).....	227
10.4.2	Divisor register (HDIV_DIVISOR)	227
10.4.3	Quotient register (HDIV_QUOTIENT)	228
10.4.4	Remainder register (HDIV_REMAINDER)	228
10.4.5	Sign register (HDIV_SIGN).....	229
10.4.6	Status Register (HDIV_STAT)	229
11	FLASH controller (FLASH)	230
11.1	Overview	230
11.2	FLASH capacity division.....	230
11.3	Functional description	230
11.3.1	Sector Erase (Sector Erase)	231
11.3.2	Full Chip Erase (Chip Erase).....	231
11.3.3	Write operation (Program)	232
11.3.4	Read operation (Read)	234
11.4	Erase time	235
11.5	Read wait period	236
11.6	Erase and write protection	237
11.6.1	Erase and write protection bit.....	237
11.6.2	PC address erase and write protection	237
11.7	Register write protection	237
11.8	Register	238
11.8.1	TNVS parameter register (FLASH_TNVS).....	239
11.8.2	TPGS parameter register (FLASH_TPGS).....	239
11.8.3	TPROG parameter register (FLASH_TPROG).....	240
11.8.4	TSERASE register (FLASH_TSERASE)	240
11.8.5	TMERASE parameter register (FLASH_TMERASE).....	241
11.8.6	TPRCV parameter register (FLASH_TPRCV)	241
11.8.7	TSRCV parameter register (FLASH_TSRCV).....	242
11.8.8	TMRCV parameter register (FLASH_TMRCV)	242

11.8.9	CR register (FLASH_CR)	243
11.8.10	IFR register (FLASH_IFR)	243
11.8.11	ICLR register (FLASH_ICLR)	244
11.8.12	BYPASS register (FLASH_BYPASS).....	244
11.8.13	SLOCK0 register (FLASH_SLOCK0)	245
11.8.14	SLOCK1 register (FLASH_SLOCK1)	245
12	RAM controller (RAM).....	246
12.1	Overview	246
12.2	Functional description	246
12.2.1	RAM address range	246
12.2.2	Read and write bit width.....	246
12.2.3	Parity	246
12.3	Register.....	247
12.3.1	Control Register (RAM_CR).....	248
12.3.2	Parity Error Address Register (RAM_ERRADDR)	248
12.3.3	Error Interrupt Flag Register (RAM_IFR)	249
12.3.4	Error Interrupt Flag Clear Register (RAM_ICLR)	249
13	DMA controller DMAC.....	250
13.1	Introduction to DMAC	250
13.2	DMAC main characteristics.....	250
13.3	Functional block diagram	251
13.4	Functional description	251
13.4.1	DMAC transfer modes.....	251
13.4.2	DMA software block transfer mode.....	252
13.4.3	DMA software Burst transfer mode.....	253
13.4.4	DMA hardware block transfer mode.....	254
13.4.5	DMA hardware Burst transfer mode.....	255
13.4.6	DMA transfer paused	256
13.4.7	DMA other configuration.....	257
13.4.8	DMA interrupt	257
13.5	Register.....	259
13.5.1	DMAC_CONF.....	260
13.5.2	DMAC_CONFA0、DMAC_CONFA1.....	261
13.5.3	DMAC_CONFB0、DMAC_CONFB1.....	263
13.5.4	DMAC_SRCADR0、DMAC_SRCADR1.....	265
13.5.5	DMAC_DSTADR0、DMAC_DSTADR1	265

14 General purpose timer (TIM0/1/2/3)	266
14.1 Introduction to General-Purpose Timers	266
14.1.1 Basic Features (TIM0/1/2)	266
14.1.2 Basic Features (TIM3).....	267
14.2 Timer function description.....	268
14.2.1 Timer clock	268
14.2.2 Timer counter	268
14.2.3 Timer Prescaler.....	268
14.2.4 Mode 0 count timer function.....	269
14.2.5 Mode 1 pulse width measurement PWC.....	272
14.2.6 Mode 2/3 compare capture mode.....	276
14.2.7 Mode 2/3 Slave Mode.....	298
14.2.8 Quadrature code counting function	299
14.2.9 Timer triggers ADC	301
14.2.10 Brake control	302
14.2.11 Timer interconnection.....	303
14.2.12 GATE input interconnection	303
14.2.13 ETR input interconnection.....	304
14.2.14 CHx capture input interconnect	304
14.2.15 DMA	305
14.3 Timer register description	307
14.4 Mode 0 Timer Register Description.....	308
14.4.1 16 -bit Mode Reload Register (TIMx_ARR)	308
14.4.2 16 -bit Mode Count Register (TIMx_CNT)	308
14.4.3 32 -bit mode count register (TIMx_CNT32)	309
14.4.4 Control Register (TIMx_M0CR).....	310
14.4.5 Interrupt Flag Register (TIMx_IFR).....	311
14.4.6 Interrupt Flag Clear Register (TIMx_ICLR)	311
14.4.7 Dead Time Register (TIMx_DTR)	312
14.5 Pulse Width Measurement PWC Register Description	313
14.5.1 16 -bit Mode Count Register (TIMx_CNT)	313
14.5.2 Control Register (TIMx_M1CR).....	314
14.5.3 Interrupt Flag Register (TIMx_IFR).....	315
14.5.4 Interrupt Flag Clear Register (TIMx_ICLR)	315
14.5.5 Master-Slave Mode Control Register (TIMx_MSCR).....	316
14.5.6 Output Control Filtering (TIMx_FLTR)	317
14.5.7 Control Register (TIMx_CR0)	318
14.5.8 Compare Capture Register (TIMx_CCR0A)	318

14.6 Mode 2,3 register description.....	319
14.6.1 16-bit Mode Reload Register (TIMx_ARR).....	319
14.6.2 16-bit Mode Count Register (TIMx_CNT).....	319
14.6.3 Control Register(TIMx_M23CR).....	320
14.6.4 Interrupt Flag Register (TIMx_IFR).....	322
14.6.5 Interrupt Flag Clear Register (TIMx_ICLR).....	323
14.6.6 Master-Slave Mode Control Register (TIMx_MSCR).....	324
14.6.7 Output Control / Input Filtering (TIMx_FLTR).....	325
14.6.8 ADC Trigger Control Register (TIMx_ADTR)	327
14.6.9 Channel 0 Control Register (TIMx_CRCH0).....	328
14.6.10 Channel 1/2 Control Registers (TIM3_CRCH1/2) (TIM3 present only)	330
14.6.11 Dead Time Register (TIMx_DTR)	332
14.6.12 Repeat cycle setting value (TIMx_RCR).....	333
14.6.13 Channel 0 Compare Capture Register (TIMx_CCR0A/B)	333
14.6.14 Channel 1/2 compare capture register (TIM3_CCR1/2 A/B) (TIM3 exists only)	334
15 Programmable Count Array (PCA)	335
15.1 Introduction to PCA.....	335
15.2 PCA function description	335
15.2.1 PCA Timer / Counter.....	336
15.2.2 PCA capture function	338
15.2.3 PCA comparison function.....	339
15.3 Interconnection and control of PCA module and other modules.....	345
15.4 PCA register description	346
15.4.1 Control Register (PCA_CCON).....	347
15.4.2 Mode Register (PCA_CMOD).....	348
15.4.3 Count register (PCA_CNT)	349
15.4.4 Interrupt Clear Register (PCA_ICLR)	349
15.4.5 Compare Capture Mode Register (PCA_CCAPM0~4)	350
15.4.6 Compare the upper 8 bits of the capture data register (PCA_CCAP0~4H).....	351
15.4.7 Compare the lower 8 bits of the capture data register (PCA_CCAP0~4L)	351
15.4.8 Compare capture 16-bit register (PCA_CCAP0~4)	352
15.4.9 Compare High Speed Output Flag Register (PCA_CCAPO)	352
15.4.10 Period Register (PCA_CARR).....	353
15.4.11 Enhanced PWM Control (PCA_EPWM).....	353
16 Advanced Timer (TIM4/5/6).....	354
16.1 Introduction to Advanced Timer	354
16.2 Advanced Timer Function Description	356
16.2.1 Basic action	356

16.2.2	Timer selection	358
16.2.3	Counting direction	359
16.2.4	Digital filtering	359
16.2.5	Software synchronization.....	360
16.2.6	Hardware synchronization	362
16.2.7	Cache function.....	364
16.2.8	General PWM output.....	365
16.2.9	Orthogonal coding count	371
16.2.10	Periodic interval response.....	376
16.2.11	Protection mechanism	377
16.2.12	Interrupt Description.....	377
16.2.13	DMA	378
16.2.14	brake protection	379
16.2.15	interconnection.....	380
16.3	Register description.....	383
16.3.1	Common Count Reference Register (TIMx_CNTER)	385
16.3.2	Universal Period Reference Register (TIMx_PERAR)	385
16.3.3	General purpose period buffer register (TIMx_PERBR).....	386
16.3.4	Universal Compare Base Registers (TIMx_GCMAR-GCMDR).....	386
16.3.5	Dedicated Compare Reference Registers (TIMx_SCMAR-SCMBR).....	387
16.3.6	DEAD TIME REFERENCE REGISTER (TIMx_DTUAR-DTDAR)	387
16.3.7	General Control Register (TIMx_GCONR).....	388
16.3.8	Interrupt Control Register (TIMx_ICONR).....	389
16.3.9	Port Control Register (TIMx_PCONR)	390
16.3.10	Buffer Control Register (TIMx_BCONR).....	392
16.3.11	Dead Time Control Register (TIMx_DCONR)	393
16.3.12	Filter Control Register (TIMx_FCONR)	394
16.3.13	Valid Period Register (TIMx_VPERR)	395
16.3.14	Status Flag Register (TIMx_STFLR).....	396
16.3.15	Hardware Start Event Select Register (TIMx_HSTAR)	397
16.3.16	Hardware Stop Event Select Register (TIMx_HSTPR)	399
16.3.17	Hardware Clear Event Select Register (TIMx_HCELR)	401
16.3.18	Hardware Capture A Event Select Register (TIMx_HCPAR).....	403
16.3.19	Hardware Capture B Event Select Register (TIMx_HCPBR).....	404
16.3.20	Hardware Increment Event Select Register (TIMx_HCUPR)	405
16.3.21	Hardware Decrement Event Select Register (TIMx_HCDOR)	407
16.3.22	Software Synchronization Start Register (TIMx_SSTAR)	409
16.3.23	Software Sync Stop Register (TIMx_SSPPR)	409

16.3.24 Software Synchronous Clear Register (TIMx_SCLR)	410
16.3.25 Interrupt Flag Register (TIMx_IFR).....	411
16.3.26 Interrupt Flag Clear Register (TIMx_ICLR)	412
16.3.27 Spread spectrum and interrupt trigger selection (TIMx_CR)	413
16.3.28 AOS Selection Control Register (TIMx_AOSSR).....	414
16.3.29 AOS Selection Control Register Flag Clear (TIMx_AOSCL)	415
16.3.30 Port Brake Control Register (TIMx_PTAKS)	416
16.3.31 Port Trigger Control Register (TIMx_TTRIG)	417
16.3.32 AOS Trigger Control Register (TIMx_ITRIG).....	418
16.3.33 Port Brake Polarity Control Register (TIMx_PTAKP).....	419
17 Watchdog Timer (WDT)	420
17.1 Introduction to WDT	420
17.2 WDT Functional Description	420
17.2.1 Interrupt generated after WDT overflow.....	420
17.2.2 Reset after WDT overflow	421
17.3 WDT register description	422
17.3.1 WDT Clear Control Register (WDT_RST).....	423
17.3.2 WDT_CON register	423
18 General Synchronous Asynchronous Transceiver (UART).....	424
18.1 Introduction	424
18.2 Main characteristics	424
18.3 Functional description	425
18.3.1 Operating mode.....	425
18.3.2 Baud rate generation.....	429
18.3.3 Frame error detection	433
18.3.4 Multi-machine communication.....	433
18.3.5 DMAC hardware handshake	434
18.3.6 Hardware flow control.....	434
18.3.7 Transceiver buffer	436
18.4 Register	438
18.4.1 Data Register (UARTx_SBUF)	439
18.4.2 Control Register (UARTx_SCON).....	440
18.4.3 Address Register (UARTx_SADDR)	441
18.4.4 Address Mask Register (UARTx_SADEN).....	441
18.4.5 Flag Register (UARTx_ISR).....	442
18.4.6 Flag Clear Register (UARTx_ICR)	442
18.4.7 Baud Rate Register (UARTx_SCNT)	443
19 Low Power Synchronous Asynchronous Transceiver (LPUART)	444

19.1	Introduction	444
19.2	Main characteristics	445
19.3	Functional description	445
19.3.1	Configuration Clock and Transmit Clock.....	445
19.3.2	Operating mode.....	446
19.3.3	Baud rate generation.....	450
19.3.4	Frame error detection	454
19.3.5	Multi-machine communication.....	454
19.3.6	DMAC hardware handshake	455
19.3.7	Hardware flow control.....	455
19.3.8	Transceiver buffer	457
19.4	Register	459
19.4.1	Data Register (LPUARTx_SBUF).....	460
19.4.2	Control register (LPUARTx_SCON)	461
19.4.3	Address Register (LPUARTx_SADDR).....	462
19.4.4	Address Mask Register (LPUARTx_SADEN)	462
19.4.5	Flag Bit Register (LPUARTx_ISR)	463
19.4.6	Flag Clear Register (LPUARTx_ICR)	463
19.4.7	Baud Rate Register (LPUARTx_SCNT)	464
20	Cyclic redundancy check (CRC)	465
20.1	Overview	465
20.2	Main characteristics	465
20.3	Functional description	465
20.3.1	Operating mode.....	465
20.3.2	Encoding	465
20.3.3	Write bit width	465
20.4	Programming example	466
20.4.1	CRC-16 encoding mode	466
20.4.2	CRC-16 check mode.....	466
20.4.3	CRC-32 encoding mode	466
20.4.4	CRC-32 check mode.....	466
20.5	Register description.....	468

24.7.2	I2Sx Status Register (I2Sx_SR).....	526
24.7.3	I2Sx Configuration Register (I2Sx_CFGR).....	527
24.7.4	I2Sx Prescaler Register (I2Sx_PR)	528
24.7.5	I2Sx Interrupt Status Clear Register (I2Sx_ICR)	529
24.7.6	I2Sx Data Register L (I2Sx_DRL)	529

24.7.7 I2Sx Data Register R (I2Sx_DRR)	530
25 USB2.0 Full Speed Module (USBFS)	531
25.1 Introduction to USBFS.....	531
25.2 Main Features of USBFS.....	531
25.2.1 General features	531
25.2.2 Device Mode Properties	531
25.3 USBFS System Block Diagram	532
25.4 USBFS pin description	532
25.5 USBFS function description	533
25.5.1 USBFS clock and working mode.....	533
25.5.2 USBFS device capabilities.....	533
25.5.3 USBFS power control.....	537
25.5.4 USBFS data FIFO	537
25.5.5 USBFS device FIFO architecture.....	538
25.5.6 USBFS FIFO RAM allocation.....	539
25.5.7 USBFS system performance.....	539
25.5.8 USBFS interrupt and Events.....	540
25.6 USBFS programming model.....	540
25.6.1 USBFS module initialization	540
25.6.2 USBFS device initialization.....	541
25.6.3 USBFS device soft disconnect operation.....	541
25.6.4 Endpoint initialization on USB reset.....	542
25.6.5 USB enumeration completes	542
25.6.6 Endpoint initialization when a SetAddress command is received	543
25.6.7 Endpoint initialization when a SetConfiguration/SetInterface command is received	543
25.6.8 Endpoint activation (Active).....	543
25.6.9 Endpoint inactive (Deactive).....	544
25.6.10 Disable (Disable) output endpoint	544
25.6.11 Pause (Stall) asynchronous output endpoint.....	544
25.6.12 Global output endpoint NAK mode	545
25.6.13 Output endpoint transmission stopped.....	545
25.6.14 Configure the interrupt input endpoint as a periodic or aperiodic endpoint (shared FIFO mode)	545
25.6.15 Global aperiodic input endpoint NAK mode (shared FIFO mode)	546
25.6.16 NAK occurred	546
25.6.17 Disable non-periodic input endpoints (Shared FIFO mode)	546
25.6.18 Disable cycle input endpoint (Shared FIFO mode)	547

25.6.19 Aperiodic input data transfer timeout (shared FIFO mode).....	547
25.6.20 Non-synchronous input endpoint pause (shared FIFO mode)	547
25.6.21 Input endpoint transfer stop (shared FIFO mode).....	548
25.6.22 Endpoint mismatch (shared FIFO mode).....	548
25.6.23 Control transfer.....	548
25.6.24 Output data transfer.....	554
25.6.25 No threshold for acyclic bulk-in data transfer	555
25.6.26 Thresholds for acyclic bulk-in data transfers	555
25.6.27 Asynchronous output data transfer without threshold.....	555
25.6.28 Asynchronous output data transfers with threshold	555
25.6.29 Synchronous output data transfer with threshold.....	555
25.6.30 Synchronous output data transfer not completed	556
25.6.31 Periodic input data transfer without threshold.....	556
25.6.32 Periodic input data transfers have thresholds.....	557
25.7 Register description.....	558
25.7.1 USBFS global registers.....	560
25.7.2 USBFS Device Mode Register.....	573
25.7.3 USBFS Clock Gating Control Register.....	601
26 Controller Area Network (CAN)	602
26.1 Introduction	602
26.2 CAN System Block Diagram.....	603
26.3 Pin description	603
26.4 Functional description	603
26.4.1 Baud rate setting	603
26.4.2 Send buffer	605
26.4.3 Receive buffer.....	605
26.4.4 Receive Filter Register Set	606
26.4.5 Data transmission.....	607
26.4.6 Single data transmission.....	607
26.4.7 Cancel data sending	607
26.4.8 Data reception	608
26.4.9 Error handling	608
26.4.10 Node down.....	609
26.4.11 Lost Arbitration Position Capture	609
26.4.12 Loop mode	609
26.4.13 Silent mode.....	610
26.4.14 Software reset function.....	611
26.4.15 Upward compatible with CAN-FD function	612

26.4.16 Time-triggered TTCAN.....	612
26.4.17 Interrupt.....	615
26.5 Register description.....	616
26.5.1 CAN receive BUF register (CAN_RBUF).....	618
26.5.2 CAN transmit BUF register (CAN_TBUF)	620
26.5.3 CAN Configuration and Status Register (CAN_CFG_STAT)	622
26.5.4 CAN Command Register (CAN_TCMD).....	623
26.5.5 CAN Transmit Control Register (CAN_TCTRL)	625
26.5.6 CAN Receive Control Register (CAN_RCTRL)	626
26.5.7 CAN Receive and Transmit Interrupt Enable Register (CAN_RTIE)	627
26.5.8 CAN Receive and Transmit Interrupt Status Register (CAN_RTIF).....	628
26.5.9 CAN Error Interrupt Enable and Flags Register (CAN_ERRINT)	629
26.5.10 CAN Bit Timing Register (CAN_BT)	630
26.5.11 CAN Error and Arbitration Lost Capture Register (CAN_EALCAP)	631
26.5.12 CAN Warning Limit Register (CAN_LIMIT).....	631
26.5.13 CAN Receive Error Counter Register (CAN_RECNT).....	632
26.5.14 CAN Transmit Error Counter Register (CAN_TECNT)	632
26.5.15 CAN Filter Group Control Register (CAN_ACFCTRL)	633
26.5.16 CAN Filter Group Enable Register (CAN_ACFEN)	634
26.5.17 CAN filter group code and mask registers (CAN_ACF).....	635
26.5.18 TTCAN TB slot pointer register (CAN_TBSLOT)	636
26.5.19 TTCAN Time Triggered Configuration Register (CAN_TTCFG).....	637
26.5.20 TTCAN Reference Message Register (CAN_REF_MSG)	638
26.5.21 TTCAN Trigger Configuration Register (CAN_TRG_CFG).....	639
26.5.22 TTCAN Trigger Time Register (CAN_TRG_TRIG)	640
26.5.23 TTCAN Trigger Watchdog Time Register (TRG_WTRIG).....	640
26.6 Precautions for use.....	641
26.6.1 CAN bus anti-jamming measures.....	641
26.6.2 CAN Controller Noise Constraints.....	641
27 Analog-to-digital converter (ADC)	642
27.1 Module Introduction.....	642
27.2 ADC block diagram.....	642
27.3 Conversion Timing and Conversion Speed	643
27.4 Single conversion mode	643
27.5 Scan conversion mode	645
27.5.1 Sequential Scan Conversion Mode.....	645
27.5.2 In-queue scan conversion mode	648
27.5.3 Scan conversion triggers DMA read.....	651

27.6	Continuous Conversion Accumulation Mode.....	651
27.7	ADC conversion external trigger source	654
27.8	ADC conversion result comparison.....	655
27.9	ADC Interrupt	656
27.10	Measure ambient temperature using a temperature sensor	656
27.11	ADC module registers.....	658
27.11.1	ADC Basic Configuration Register 0 (ADC_CR0).....	660
27.11.2	ADC Basic Configuration Register 1 (ADC_CR1).....	662
27.11.3	ADC Sequential Scan Conversion Channel Configuration Register 0 (ADC_SQR0) .663	
27.11.4	ADC Sequential Scan Conversion Channel Configuration Register 1 (ADC_SQR1) .664	
27.11.5	ADC Sequential Scan Conversion Channel Configuration Register 2 (ADC_SQR2) .665	
27.11.6	ADC jumping scan conversion channel configuration register (ADC_JQR)	666
27.11.7	ADC sequential scan conversion channel x conversion result (ADC_SqrResult0 - 15) 666	
27.11.8	ADC jump scan conversion channel x conversion result (ADC_JqrResult0 - 3)	667
27.11.9	ADC conversion result (ADC_Result)	667
27.11.10	Accumulated value of ADC conversion result (ADC_ResultAcc)	668
27.11.11	ADC Compare Upper Threshold (ADC_HT)	668
27.11.12	ADC Compare Lower Threshold (ADC_LT)	669
27.11.13	ADC Interrupt Flag Register (ADC_IFR)	670
27.11.14	ADC Interrupt Clear Register (ADC_ICR)	671
27.11.15	ADC single conversion or sequential scan conversion external interrupt trigger source configuration register (ADC_ExtTrigger0)	672
27.11.16	ADC jump scan conversion external interrupt trigger source configuration register (ADC_ExtTrigger1)	674
27.11.17	ADC Single Conversion Start Control Register (ADC_SglStart).....	676
27.11.18	ADC Sequential Scan Conversion Start Control Register (ADC_SqrStart).....	676
27.11.19	ADC jump scan conversion start control register (ADC_JqrStart)	677
27.11.20	ADC has been converting start stop control register (ADC_allStart)	677
28	Digital to Analog Converter (DAC).....	678
28.1	DAC Characteristic	678
28.2	Functional description	679
28.2.1	Block diagram.....	679
28.2.2	DAC output buffer enable	680
28.2.3	DAC channel enable.....	680
28.2.4	DAC output voltage.....	680
28.2.5	DAC trigger selection	680
28.2.6	Single mode function description	681

28.2.7	Dual mode function description	683
28.2.8	Noise generation.....	688
28.2.9	Triangle wave generation.....	688

Overview

The HC32F072 series is a general MCU with a wide voltage operating range. Integrate 12-bit 1Msps high-precision SARADC, 2 12-bit DACs and integrated comparator, operational amplifier, built-in high-performance PWM timer, multiple UART, SPI, I2C, I2S, USB, CAN and other rich communications. It has built-in information security modules such as AES and TRNG, which have the characteristics of high integration, high anti-interference and high reliability. The core of this product adopts the Cortex-M0+ core, cooperates with mature Keil & IAR debugging and development software, supports C language, assembly language, and assembly instructions.

General MCU typical applications

It can be widely used in various market applications: such as human-computer interaction, handheld devices, game peripherals, printers, video intercom and other smart home applications.

About this manual

This manual mainly introduces the function, operation and usage of the chip. For chip specifications, please refer to the corresponding "Datasheet".

1 System Structure

1.1 Overview

This product system consists of the following parts:

- 2 AHB bus masters:
 - Cortex-M0+
 - DMA controller
- 4 AHB bus slaves:
 - FLASH memory
 - SRAM memory
 - AHB0, AHB to APB Bridge, including all APB interface peripherals
 - AHB1, contains all AHB interface peripherals

The entire system bus structure is realized by multi-level AHB-lite bus interconnection. As shown below:

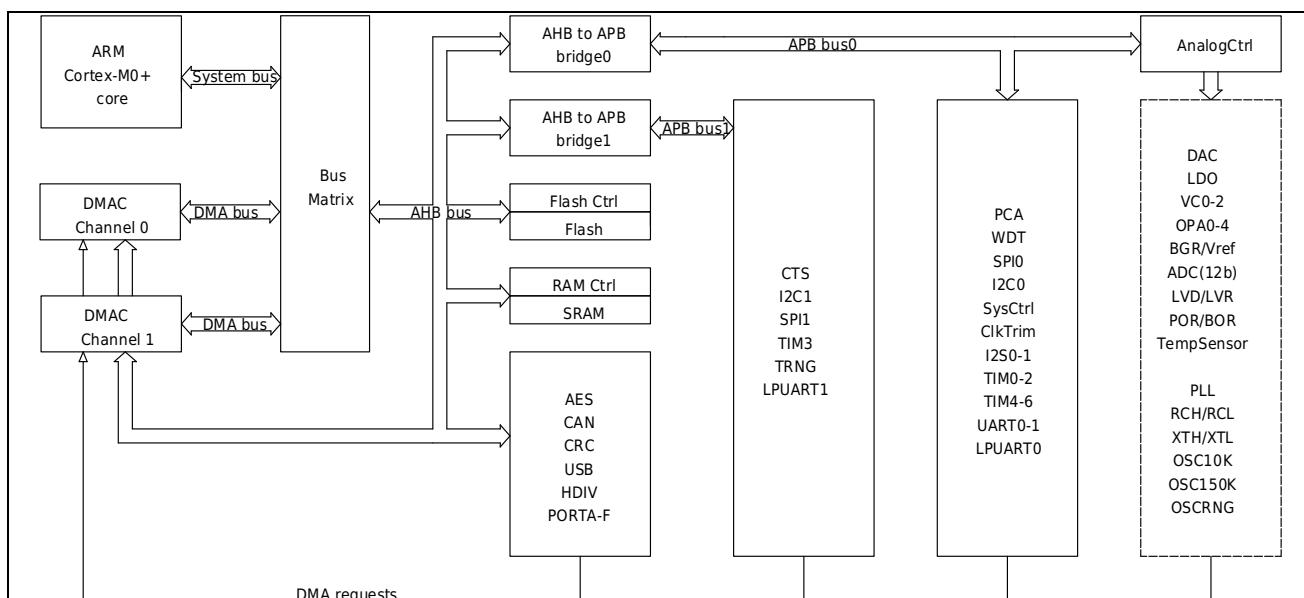

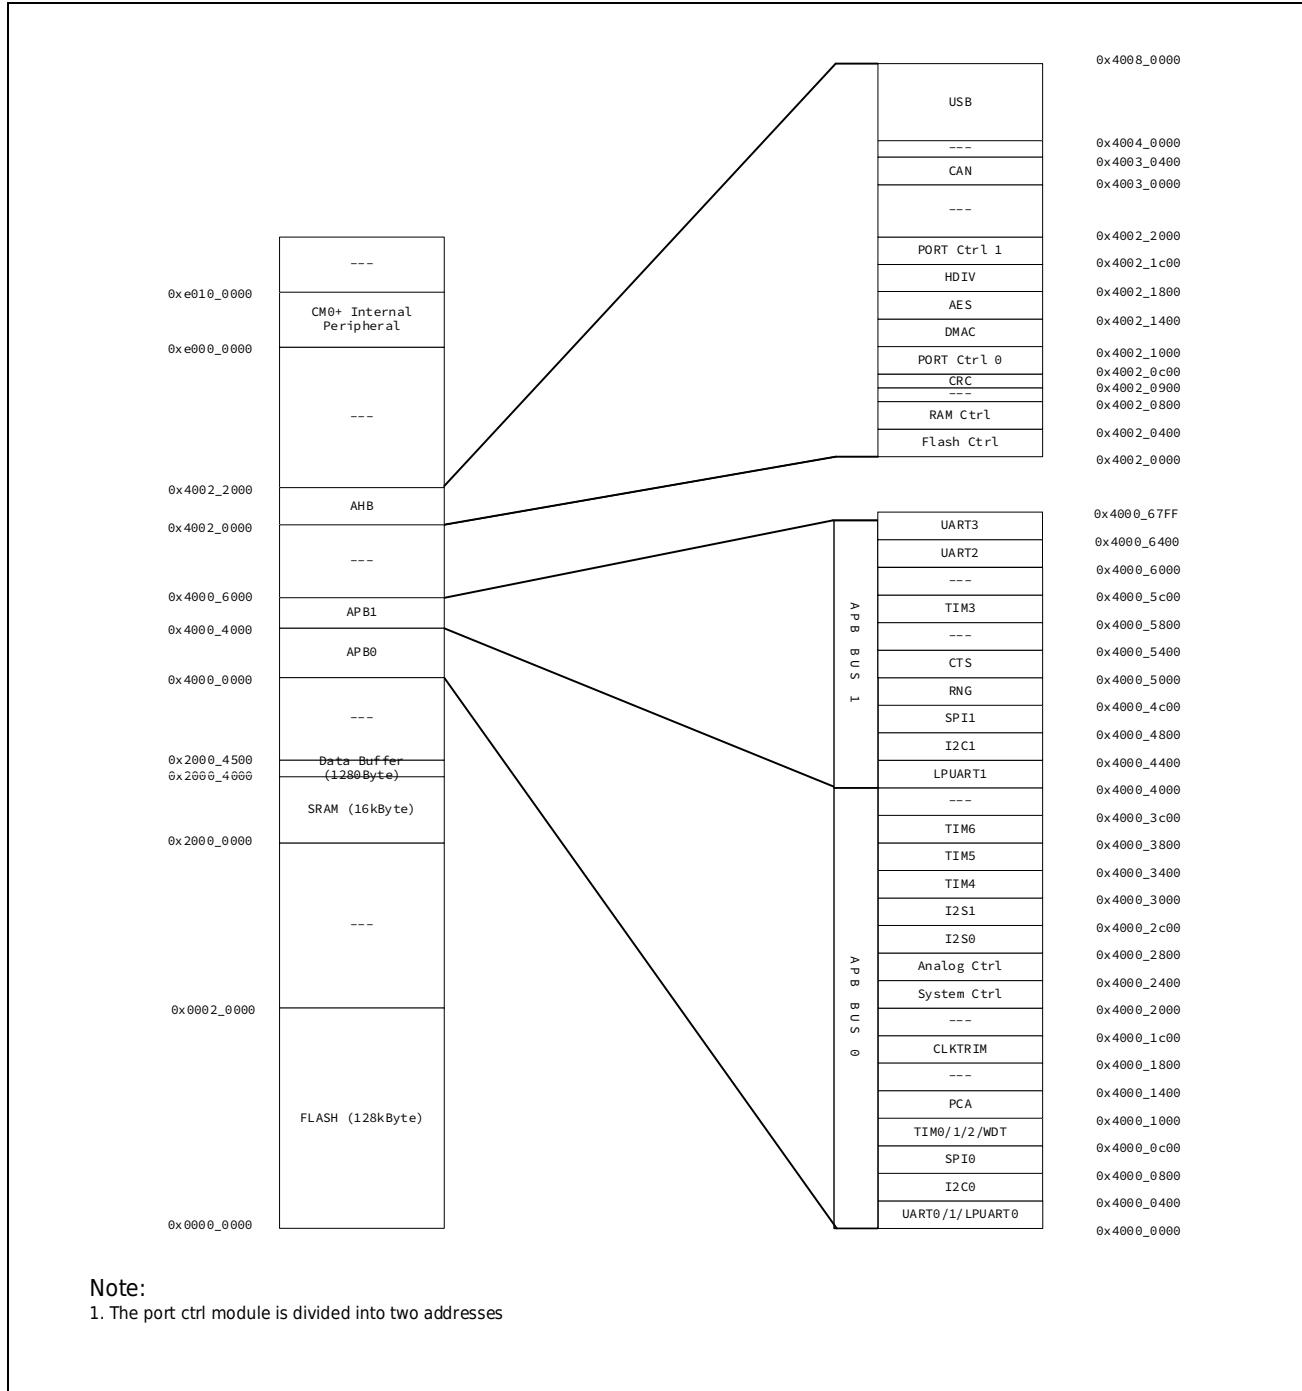

Figure 1-1 System Architecture Diagram

1.2 System address division

The address area division of the entire series of systems is shown in the following figure:

Note:

1. The port ctrl module is divided into two addresses

Figure 1-2 Schematic Diagram of Address Area division

1.3 Memory and Module Address Assignment

Table 1-1 Address Division Table

Boundary Address	Size	Memory Area	Description
0x0000_0000 - 0x0000_FFFF	128KByte	FLASH	
0x0001_0000 - 0x1FFF_FFFF	-	Reserved

2 Operating mode

The power management module of this product is responsible for managing the switching between various working modes of this product, and controlling the working status of each functional module in each working mode. The operating voltage (VCC) of this product is 1.8V ~ 5.5V.

This product has the following working modes:

- 1) Active Mode: CPU running, peripheral function modules running.
- 2) Sleep mode: The CPU stops running, and the peripheral function modules run.
- 3) Deep sleep mode: The CPU stops running, and the high-speed clock stops running.

From run mode, other low-power modes can be entered by executing a software program. From various other low-power modes, it is possible to return to run mode through an interrupt trigger.

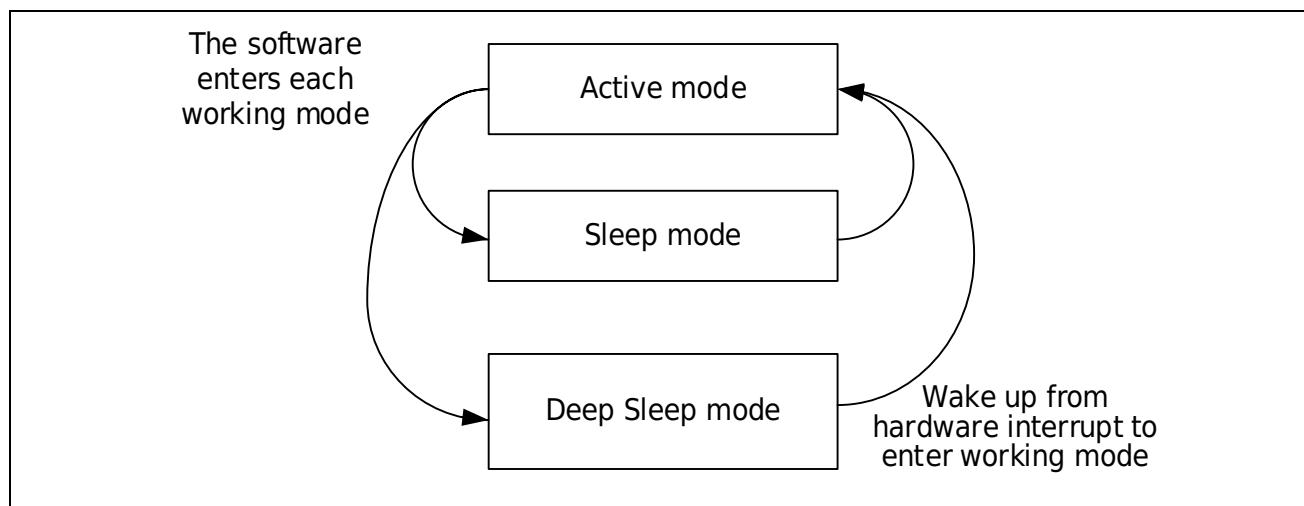

Figure 2-1 Control Mode Block Diagram

In each mode, the CPU can respond to all interrupt types:

Interrupt vector number	Interrupt source	Operating mode	Sleep mode	Deep sleep mode
[0]	GPIO_PA	✓	✓	✓
[1]	GPIO_PB	✓	✓	✓
[2]	GPIO_PC/GPIO_PE	✓	✓	✓
[3]	GPIO_PD/GPIO_PF	✓	✓	✓
[4]	DMAC	✓	✓	
[5]	TIM3	✓	✓	
[6]	UART0	✓	✓	
[7]	UART1	✓	✓	
[8]	LPUART0	✓	✓	✓
[9]	LPUART1	✓	✓	✓
[10]	SPI0/I2S0	✓	✓	
[11]	SPI1/I2S1	✓	✓	

Interrupt vector number	Interrupt source	Operating mode	Sleep mode	Deep sleep mode
[12]	I2C0	✓	✓	
[13]	I2C1	✓	✓	
[14]	TIM0	✓	✓	
[15]	TIM1	✓	✓	
[16]	TIM2	✓	✓	
[17]	-			
[18]	TIM4	✓	✓	
[19]	TIM5	✓	✓	
[20]	TIM6	✓	✓	
[21]	PCA	✓	✓	
[22]	WDT	✓	✓	✓
[23]	-			
[24]	ADC/DAC	✓	✓	
[25]	-			
[26]	VC0/VC1/VC2/LVD	✓	✓	✓

[28]	CAN	✓	✓	
[29]	-			
[30]	FLASH/RAM	✓	✓	
[31]	CLKTRIM/CTS	✓	✓	✓

In each mode, the Product responds to all reset types:

	reset source	Operating mode	Sleep mode	Deep sleep mode
[0]	Power-on brown-out reset POR	✓	✓	✓
[1]	External Reset Pin reset	✓	✓	✓
[2]	LVD reset	✓	✓	✓
[3]	WDT reset	✓	✓	✓
[4]	PCA reset	✓	✓	
[5]	Cortex-M0+ LOCKUP hardware reset	✓		
[6]	Cortex-M0+ SYSRESETREQ software reset	✓		

2.1 Operating mode

The active mode of this product:

The microcontroller MCU is in the running state after the system is reset at power-on, or after waking up from various low power consumptions. Various low-power modes are available to conserve power when the CPU is not required to continue running, such as while waiting for an external event. Users need to select an optimal low-power mode based on the lowest power consumption, fastest startup time, and available wake-up sources.

Table 2-1 Runnable module diagram in run mode

Active Mode		
Cortex-M0+	SWD	XTH
FLASH	CAN	RCH
RAM	USB	PLL
DMAC	UART0-3	ADC
TIM0-3	SPI0-1	DAC
TIM4-6	I2C0-1	TRNG
PCA	I2S0-1	OPA0-4
HDIV	CRC	LVD
AES	XTL	RESET
LPUART0-1	RCL	POR/BOR
GPIO	CLKTRIM	VC0-2
		WDT
		CTS

Several ways to reduce chip power consumption in run mode:

- 1) any one of the system clocks (HCLK, PCLK) can be slowed down by programming the prescaler registers (SYSCTRL0.HCLK_PRS, SYSCTRL0.PCLK_PRS). The prescaler can also be used to slow down the clocks to peripherals before entering Sleep mode.
- 2) In Run mode, turn off the clock (PERIx_CLKx) of unused peripherals to reduce power consumption.
- 3) In run mode, turn off the clocks of unused peripherals (PERIx_CLKx) to reduce power consumption, and put the system into sleep mode to reduce power consumption even more, and turn off the clocks of unused peripherals (PERIx_CLKEN.x).
- 4) Use low-power mode instead of sleep mode, because the wake-up time of this product is extremely short (~4us), which can also meet the real-time response requirements of the system.

2.2 Sleep mode

This product sleep mode

Use the WFI command to enter the sleep mode. In the sleep mode, the CPU stops running, but the clock module, system clock, NVIC interrupt processing and peripheral functional modules can still work.

When the system enters the dormant state, the port state will not be changed. Before entering the dormant state, the IO state can be changed to the dormant state as needed.

■ How to enter sleep mode:

Enter sleep state by executing WFI instruction. Depending on the value of the SLEEPONEXIT bit in the Cortex-M0+ System Control Register, there are two options for selecting the sleep mode entry mechanism:

SLEEP-NOW: If the SLEEPONEXIT bit is cleared, the microcontroller enters sleep mode immediately when WFI or WFE is executed.

SLEEP-ON-EXIT: If the SLEEPONEXIT bit is set, the microcontroller enters sleep mode immediately when the system exits from the lowest priority interrupt handler.

■ How to exit sleep mode:

If the WFI instruction is executed to enter the sleep mode, any peripheral interrupt responded by the high-priority nested vector interrupt controller can wake up the system from the sleep mode.

Note:

- 1) The position of SLEEP-ON-EXIT is 1, and the interrupt will automatically enter sleep after execution, and the program does not need to write `_wfi()`;
- 2) SLEEP-ON-EXIT This bit is cleared to 0, main() executes `_wfi()` and enters sleeping, interrupt triggers and executes the interrupt program and returns to main(), then executes WFI instruction and enters sleeping. Wait for a subsequent interrupt to fire.
- 3) The SLEEP-ON-EXIT bit does not affect the execution of the `_wfi()` instruction. SLEEP-ON-EXIT =0: main() enters sleeping after executing `wfi()`, interrupt triggers and returns to main() after executing the interrupt program, and then continues to execute;
- 4) If sleep is entered in an interrupt, only interrupts with a priority higher than this interrupt can wake up, and the high priority is executed first, and then the low priority is executed; interrupts with a priority lower than or equal to this interrupt cannot be woken up.

Table 2-2 Runnable Module Diagram in Sleep Mode

Sleep Mode		
Cortex-M0+	SWD	XTH
FLASH	CAN	RCH
RAM	USB	PLL
DMAC	UART0-3	ADC
TIM0-3	SPI0-1	DAC

		WDT
		CTS

Note: The modules in the gray dotted box are not working in the current state.

2.3 Deep sleep mode

This product deep sleep mode

Use SLEEPDEEP with the WFI command to enter deep sleep mode. In deep sleep mode, the CPU stops running, the high-speed clock is turned off, the low-speed clock can be configured to run or not, and some low-power peripheral modules can be configured to allow or not. NVIC interrupt processing can still work.

- When the system enters deep sleep mode from the high-speed clock, the high-speed clock is automatically turned off, and the low-speed clock remains in the state before entering deep sleep.
- The system enters the deep sleep mode from the low-speed clock, and since the low-speed clock will not be automatically shut down, it keeps running and enters the sleep mode. Only ARM Cortex-M0+ is not running, other modules are running.
- When the system clock is switched, all clocks will not be automatically turned off, and the corresponding clocks need to be turned off and turned on by software according to power consumption and system requirements.
- When the system enters the deep sleep state, it will not change the port state. Before entering the sleep state, change the IO state to the sleep state as needed.

How to enter deep sleep mode:

First set the SLEEPDEEP bit in the Cortex-M0+ system control register, and enter the sleep state by executing the WFI instruction. Depending on the value of the SLEEPONEXIT bit in the Cortex™ -M0+ System Control Register, there are two options for selecting the Deep Sleep mode entry mechanism:

SLEEP-NOW: If the SLEEPONEXIT bit is cleared, the microcontroller enters sleep mode immediately when WFI or WFE is executed.

SLEEP-ON-EXIT: If the SLEEPONEXIT bit is set, the microcontroller enters sleep mode immediately when the system exits from the lowest priority interrupt handler.

How to exit deep sleep mode:

If the WFI instruction is executed to enter sleep mode, any peripheral interrupt that is responded to by the nested vector interrupt controller (operable under Deep Sleep Peripheral module interrupt) can wake up the system from sleep mode.

Wake-up settings refer to 3.4 Interrupt Wake-Up Control WIC.

System Control Register (Cortex-M0+ Core System Control Register)

Address: 0xE000ED10

Reset value: 0x0000 0000

Bit	Marking	Functional description	Read and write
31:5	RESERVED	Keep	
4	SEVONPEND	When set to 1, an event is generated every time a new interrupt is pending, which can be used to wake up the processor if WFE sleep is used	RW
3	RESERVED	Keep	
2	SLEEPDEEP	When set to 1, implement WFI to enter deep sleep, and this product enters Deep sleep mode When set to 0, execute WFI to enter sleep mode, and this product enters sleep/Idle mode	RW
1	SLEEPONEXIT	When set to 1, the processor automatically enters sleep mode (WFI) when exiting exception handling and returning to the program thread When set to 0, the feature is automatically disabled	RW
0	RESERVED	Keep	

After entering deep sleep, there are two options for the system clock after waking up. The clock entering deep sleep is used by default. After the configuration register SYSCTRL0.wakeup_byRCH is set to 1, no matter what clock is before entering deep sleep, the internal high-speed clock RCH will be used after waking up. If you use an external crystal oscillator, this setting can speed up the wake-up of the system.

3 System Controller (SYSCTRL)

3.1 System Clock Introduction

The clock control module mainly controls the system clock and the peripheral clock. Different clock sources can be configured as the system clock, different frequency divisions of the system clock can be configured, and peripheral clocks can be enabled or disabled. To ensure oscillator accuracy, the internal clocks are calibrated.

This product supports the following five different clock sources as the system clock:

- Internal high-speed RC clock RCH (output frequency is 4~24MHz)
- Internal low-speed RC clock RCL (38.4K and 32.8K configurable)
- External high-speed crystal oscillator clock XTH
- External low-speed crystal oscillator clock XTL
- Phase-locked loop clock PLL

Note 1: When switching the clock source of the system clock, please strictly follow the operation steps to switch, see Chapter 5.2 for details.

Note 2: XTL can directly input 32.768kHz clock signal from PC14 pin without crystal oscillator. XTH can not be connected to the crystal oscillator, and directly input the 4~32MHz clock signal from the PF00 pin.

This product also contains the following three auxiliary clocks:

- The internal low-speed 10K clock is only used by the watchdog and CLKTRIM modules.
- The internal 150K clock is only used by LVD and VC modules.
- The internal 48M clock is only used by the USB module and can be automatically calibrated by the CTS module.

The figure below shows the clock architecture of this product.

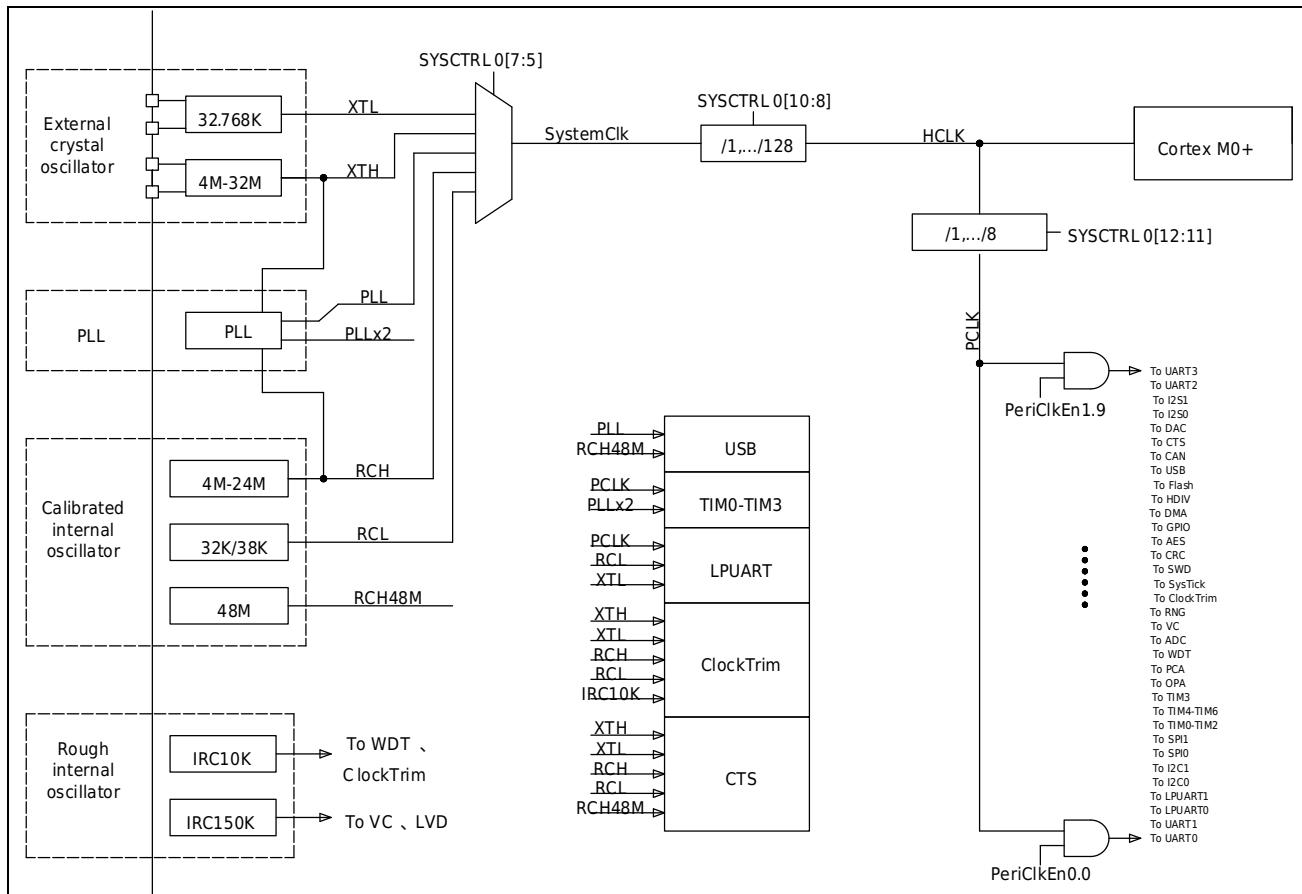

Figure 3-1 Clock Control Module Block Diagram

3.1.1 Internal high speed RC clock RCH

The default clock source after the chip is powered on or reset is an internal high-speed clock with a frequency of 4 MHz, an internal high-speed clock with a frequency of 4MHz. when the system enters Deep Sleep, this high-speed clock will be automatically turned off.

The output frequency of RCH can be adjusted by changing the value of the register RCH_CR[10:0]. Every time the register value increases by 1, the output frequency of RCH will increase by about 0.2%, and the total adjustment range is 4~24MHz.

Five frequencies 4MHz, 8MHz, 16MHz, 22.12MHz, and 24MHz have been preset before leaving the factory; if you need other frequencies, please manually adjust the value of this register.

Changing the RCH output frequency needs to follow a specific change timing, see the chapter on system clock switching for details.

The internal high-speed clock only needs 4us from startup to stabilization. In order to respond to interrupts quickly in deep sleep mode, it is recommended to switch the system clock to RCH before entering deep sleep mode.

3.1.2 Internal low speed RC clock RCL

The output frequency of the internal low-speed clock can be selected through the register RCL_CR[9:0]. The available frequencies are 38.4KHz and 32.768KHz. When the system enters Deep Sleep, this low-speed clock will not be automatically turned off, and the ultra-low power peripheral module can choose RCL as its clock.

3.1.3 External low-speed crystal oscillator clock XTL

The external low-speed crystal oscillator clock requires an external 32.768KHz low-power crystal oscillator, which has ultra-high precision and ultra-low power consumption. When the system enters Deep Sleep, the low-speed clock will not be turned off automatically. Peripheral modules operating in ultra-low power mode can select XTL as their clock.

XTL can also not be connected to the crystal oscillator, and directly input the 32.768KHz clock signal from the PC14 pin. The method of inputting clock signal from PC14 is: configure PC14 pin as GPIO input; set SYSCTRL1. EXTL_EN to 1.

Note:

- The crystal and its matching devices must meet the relevant requirements of the **low-speed external clock XTL in the electrical characteristics of the data sheet**.

3.1.4 External high-speed crystal oscillator clock XTH

The external high-speed crystal oscillator clock needs to be connected with a 4~32MHz high-speed crystal oscillator. When the system enters Deep Sleep, this high-speed clock will be automatically turned off.

XTH can also not be connected to the crystal oscillator, and directly input the 4~32MHz clock signal from the PF00 pin. The method of inputting clock signal from PF00 is: configure PF00 pin as GPIO input; set SYSCTRL1. EXTH_EN to 1.

Note:

- The crystal and its matching devices must meet the relevant requirements of the **high-speed external clock XTH in the electrical characteristics of the data sheet**.
- In order to ensure the high reliability of XTH work, it is strongly recommended to use an external active crystal oscillator.

3.1.5 Phase-locked loop clock PLL

Built-in PLL supports 8~48MHz clock output. The reference clock sources of the PLL are: RCH, XTH crystal oscillator clock, and PF00 pin input clock.

PLL has a power consumption of about tens of microamps in deep sleep mode. It is recommended to configure the system clock as RCH/XTH and turn off PLL and BGR before entering deep sleep mode. After waking up, reconfigure the system clock as PLL.

3.1.6 Internal high speed clock RCH48M

The internal high-speed clock RCH48M can be used as the clock for crystal-less USB, and it can be automatically calibrated by using the module CTS. Cannot be used as system clock.

3.1.7 Clock start process

The above five clock sources all require startup stabilization time. The following figure uses the external XTH as an example to illustrate the clock startup stabilization process.

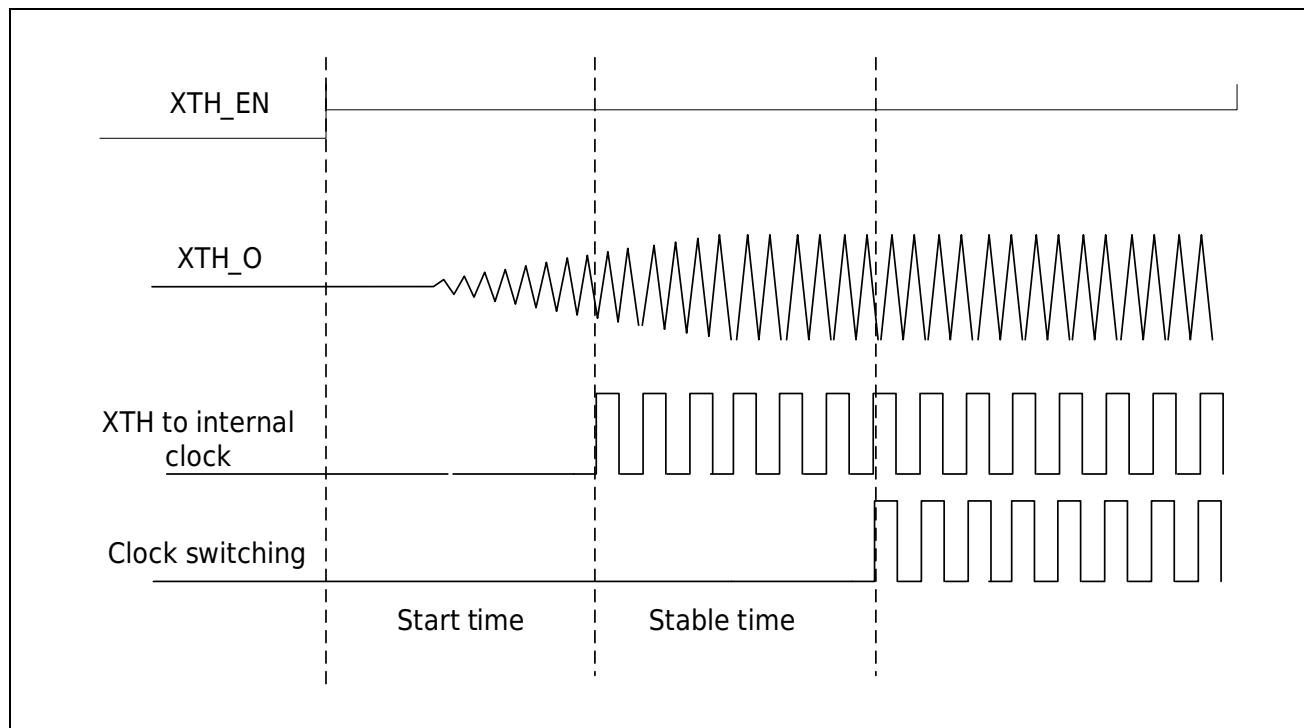

Figure 3-2 Schematic diagram of crystal oscillator clock startup

3.2 System Clock Switching

The switching of the clock source is controlled by the register SYSCTRL0[7:0]. The clock source of the system clock can be switched among RCH, RCL, XTH, XTL, and PLL through SYSCTRL0[7:5]. Any two of the four clock sources RCH, RCL, XTH, and XTL can be switched with each other during switching; the PLL can only be switched with the two clocks of RCH and XTH. The clock switching operation must be performed according to the seven clock switching processes described below, otherwise abnormalities may occur.

FLASH_CR.WAIT needs to be configured synchronously when the clock is switched. If the clock frequency is not greater than 24MHz, FLASH_CR.WAIT should be set to 0; if the clock frequency is

greater than 24MHz, FLASH_CR.WAIT should be set to 1; if the clock frequency is greater than 48MHz, FLASH_CR.WAIT should be set to 2.

Note: To set the value of FLASH_CR.WAIT, you need to write 0x5A5A and 0xA5A5 to the FLASH_BYPASS register in sequence, and then assign a value to FLASH_CR.WAIT. For details, see the FLASH controller chapter.

3.2.1 Standard Clock Switching Process

The operation process is as follows:

Step1: If the new clock source requires an external pin, set the pin to an appropriate mode.

Note: An analog pin is required when connecting to an external crystal oscillator; GPIO input is required and the external clock input is enabled when connecting to an external clock input.

Step2: Configure the oscillation parameters of the new clock source.

Step3: Enable the oscillator of the new clock source.

Step4: According to the higher frequency of the current clock source and the new clock source, configure FLASH_CR.WAIT according to the procedures in the Flash controller chapter.

Step5: Wait for the new clock source to output a stable frequency.

Step6: Configure SYSCtrl0.CLKSW, select the source of the system clock as the new clock source.

Step7: According to the frequency of the new clock source, configure FLASH_CR.WAIT according to the procedures in the Flash controller chapter.

Step8: Turn off the clock source that is no longer used.

3.2.2 RCH switching process between different oscillation frequencies

There are two schemes for switching between different oscillation frequencies of the RCH.

Scheme 1:

Step1: Write 0x5A5A and 0xA5A5 to the SYSCtrl2 register in sequence to enable register rewriting.

Step2: Set SYSCtrl0.HCLK_PRS to 0x7.

Step3: Adjust the output frequency of RCH step by step up or down, 4M -> 8M -> 16M -> 24M/22.12M or 24M/22.12M -> 16M -> 8M -> 4M.

Step4: Write 0x5A5A and 0xA5A5 to the SYSCtrl2 register in sequence to enable register rewriting.

Step 5: Set SYSCtrl0.HCLK_PRS is 0x0.

M0P_SystemCtrl->SYSCtrl2 = 0X5A5A;

M0P_SystemCtrl->SYSCtrl2 = 0XA5A5;

```
M0P_SystemCtrl->SYSCTRL0_f.HCLK_PRS = 7;  
  
M0P_SystemCtrl->RCH_CR = *((uint16 *) (0X00100C08)); //4M  
  
M0P_SystemCtrl->RCH_CR = *((uint16 *) (0X00100C06)); //8M  
  
M0P_SystemCtrl->RCH_CR = *((uint16 *) (0X00100C04)); //16M  
  
M0P_SystemCtrl->RCH_CR = *((uint16 *) (0X00100C00)); //24M  
  
M0P_SystemCtrl->SYSCTRL2 = 0X5A5A;  
  
M0P_SystemCtrl->SYSCTRL2 = 0XA5A5;  
  
M0P_SystemCtrl->SYSCTRL0_f.HCLK_PRS = 0
```

The example code for switching from 4M to 24M is as follows:

Scheme 2:

Step1: Switch the system clock to RCL, see 5.2.5 Example of switching from other clocks to RCL.

Step2: Switch the system clock to RCH, see 5.2.6 Example of switching from other clocks to RCH.

3.2.3 XTL Example from Other Clocks

The operation process is as follows:

Step1: Set PCADS. 14 and PCADS. 15 to 1, and configure PC14/PC15 pins as analog ports.

Step2: Configure XTL_CR[5:0] according to the characteristics of the crystal oscillator.

Step3: Write 0x5A5A and 0xA5A5 to the SYSCTRL2 register in sequence to enable register rewriting.

Step4: Set SYSCTRL0. XTL_EN to 1 to enable the crystal oscillator circuit.

Step5: Query and wait for the XTL_CR. Stable flag to become 1, and the crystal oscillator outputs a stable clock.

Step6: Write 0x5A5A and 0xA5A5 to the SYSCTRL2 register in sequence to enable register rewriting.

Step7: Set SYSCTRL0. CLKSW to 3, switch the system clock to XTL.

Step8: Set FLASH_CR. WAIT to 0 according to the procedures in the Flash controller chapter.

Step9: Write 0x5A5A and 0xA5A5 to the SYSCTRL2 register in sequence to enable register rewriting.

Step10: Set SYSCTRL0.xxx_EN to 0, turn off the original clock.

3.2.4 Switching from other clocks to XTH example

Step1: Set PFADS. 0 and PFADS. 1 to 1, and configure PF00/PF01 pins as analog ports.

Step2: Configure XTH_CR[3:0] according to the characteristics of the crystal oscillator.

Step3: Set XTH_CR. Startup to 3, choose the longest crystal oscillator stabilization time.

Step4: Write 0x5A5A and 0xA5A5 to the SYSCTRL2 register in sequence to enable register rewriting.

Step5: Set SYSCTRL0. XTH_EN to 1 to enable the crystal oscillator circuit.

Step6: According to the higher frequency of the current clock and XTH, configure according to the process of the Flash controller chapter

FLASH_CR.WAIT.

Step7: Query and wait for the XTH_CR. Stable flag to become 1, the software delays more than 10ms, and the crystal oscillator outputs a stable clock.

Step8: Write 0x5A5A and 0xA5A5 to the SYSCTRL2 register in sequence to enable register rewriting.

Step9: After SYSCTRL0.CLKSW is set to 1, switch the system clock to XTH.

Step10: According to the frequency of XTH, configure FLASH_CR. WAIT according to the procedures in the chapter of Flash controller.

Step11: Write 0x5A5A and 0xA5A5 to the SYSCTRL2 register in sequence to enable register rewriting.

Step12: Set SYSCTRL0.xxx_EN to 0, turn off the original clock.

3.2.5 Switching from other clocks to RCL example

The operation process is as follows:

Step1: Configure RCL_CR.TRIM and RCL_CR.Startup.

Step2: Write 0x5A5A and 0xA5A5 to the SYSCTRL2 register in sequence to enable register rewriting.

Step3: Set SYSCTRL0. RCL_EN to 1 to enable the RCL oscillator circuit.

Step4: The query waits for the RCL_CR. Stable flag to become 1, and the RCL outputs a stable clock.

Step5: Write 0x5A5A and 0xA5A5 to the SYSCTRL2 register in sequence to enable register rewriting.

Step6: Set SYSCTRL0. CLKSW to 2, switch the system clock to RCL.

Step7: Set FLASH_CR. WAIT to 0 according to the procedures in the Flash controller chapter.

Step8: Write 0x5A5A and 0xA5A5 to the SYSCTRL2 register in sequence to enable register rewriting.

Step9: Set SYSCTRL0.xxx_EN to 0, turn off the original clock.

3.2.6 Switching from other clocks to RCH example

The operation process is as follows:

Step1: Configure RCH_CR.TRIM.

Step2: Write 0x5A5A and 0xA5A5 to the SYSCTRL2 register in sequence to enable register rewriting.

Step3: Set SYSCTRL0. RCH_EN to 1 to enable the RCH oscillator circuit.

Step4: The query waits for the RCH_CR. Stable flag to become 1, and the RCH outputs a stable clock.

Step5: Write 0x5A5A and 0xA5A5 to the SYSCTRL2 register in sequence to enable register rewriting.

Step6: Set SYSCTRL0. CLKSW to 0, switch the system clock to RCH.

Step7: Set FLASH_CR. WAIT to 0 according to the procedures in the Flash controller chapter.

Step8: Write 0x5A5A and 0xA5A5 to the SYSCTRL2 register in sequence to enable register rewriting.

Step9: Set SYSCTRL0.xxx_EN to 0, turn off the original clock.

3.2.7 Example of switching between PLL and RCH, the reference clock is RCH

The process of switching from RCH to PLL is as follows:

Step1: Set BGR_CR to 0x01 and delay 20us, wait for BGR to start and stabilize.

Step2: Set PLL_CR.REFSEL to 3, select PLL clock source as RCH.

Step3: Configure PLL_CR.FRSEL according to the RCH frequency.

Step4: Configure PLL_CR.DIVN and PLL_CR.FOSC according to the PLL output frequency.

Step5: Set PLL_CR. Startup to 7, choose the longest PLL stabilization time.

Step6: Write 0x5A5A and 0xA5A5 to the SYSCTRL2 register in sequence to enable register rewriting.

Step7: Set SYSCTRL0.PLL_EN to 1 to enable the PLL oscillation circuit.

Step8: According to the PLL output frequency, configure FLASH_CR. WAIT according to the procedures in the Flash controller chapter.

Step9: Query and wait for the PLL_CR. Stable flag to become 1, and the PLL outputs a stable clock.

Step10: Write 0x5A5A and 0xA5A5 to the SYSCTRL2 register in sequence to enable register rewriting.

Step11: Set SYSCTRL0. CLKSW to 4, switch the system clock to PLL.

RCH_CR.TRIM must not be changed during switching.

The operation process of switching from PLL to RCH is as follows:

Step1: Write 0x5A5A and 0xA5A5 to the SYSCTRL2 register in sequence to enable register rewriting.

Step2: Set SYSCTRL0. CLKSW to 0, switch the system clock to RCH.

Step3: Set FLASH_CR. WAIT to 0 according to the procedures in the Flash controller chapter.

Step4: Write 0x5A5A and 0xA5A5 to the SYSCTRL2 register in sequence to enable register rewriting.

Step5: Set SYSCTRL0.PLL_EN to 0, turn off PLL.

Step6: Set BGR_CR to 0x01 to 0, turn off BGR.

RCH_CR.TRIM must not be changed during switching.

3.2.8 Example of switching between PLL and XTH, the reference clock is XTH

The process of switching from RCH to PLL is as follows:

Step1: Set BGR_CR to 0x01 and delay 20us, wait for BGR to start and stabilize.

Step2: Set PLL_CR.REFSEL to 0, select the PLL clock source as XTH.

Step3: According to XTH frequency, configure PLL_CR.FRSEL.

Step4: Configure PLL_CR.DIVN and PLL_CR.FOSC according to the PLL output frequency.

Step5: Set PLL_CR.Startup to 7, choose the longest PLL stabilization time.

Step6: Write 0x5A5A and 0xA5A5 to the SYSCTRL2 register in sequence to enable register rewriting.

Step7: Set SYSCTRL0.PLL_EN to 1 to enable the PLL oscillation circuit.

Step8: According to the PLL output frequency, configure FLASH_CR.WAIT according to the procedures in the Flash controller chapter.

Step9: Query and wait for the PLL_CR.Stable flag to become 1, and the PLL outputs a stable clock.

Step10: Write 0x5A5A and 0xA5A5 to the SYSCTRL2 register in sequence to enable register rewriting.

Step11: Set SYSCTRL0.CLKSW to 4, switch the system clock to PLL.

The operation process of switching from PLL to XTH is as follows:

Step1: Write 0x5A5A and 0xA5A5 to the SYSCTRL2 register in sequence to enable register rewriting.

Step2: Set SYSCTRL0.CLKSW to 1, switch the system clock to XTH.

Step3: According to the frequency of XTH, configure FLASH_CR.WAIT according to the procedures in the chapter of Flash controller.

Step4: Write 0x5A5A and 0xA5A5 to the SYSCTRL2 register in sequence to enable register rewriting.

Step5: Set SYSCTRL0.PLL_EN to 0, turn off PLL.

Step6: Set BGR_CR to 0x01 to 0, turn off BGR.

The following figure is the clock switching timing diagram:

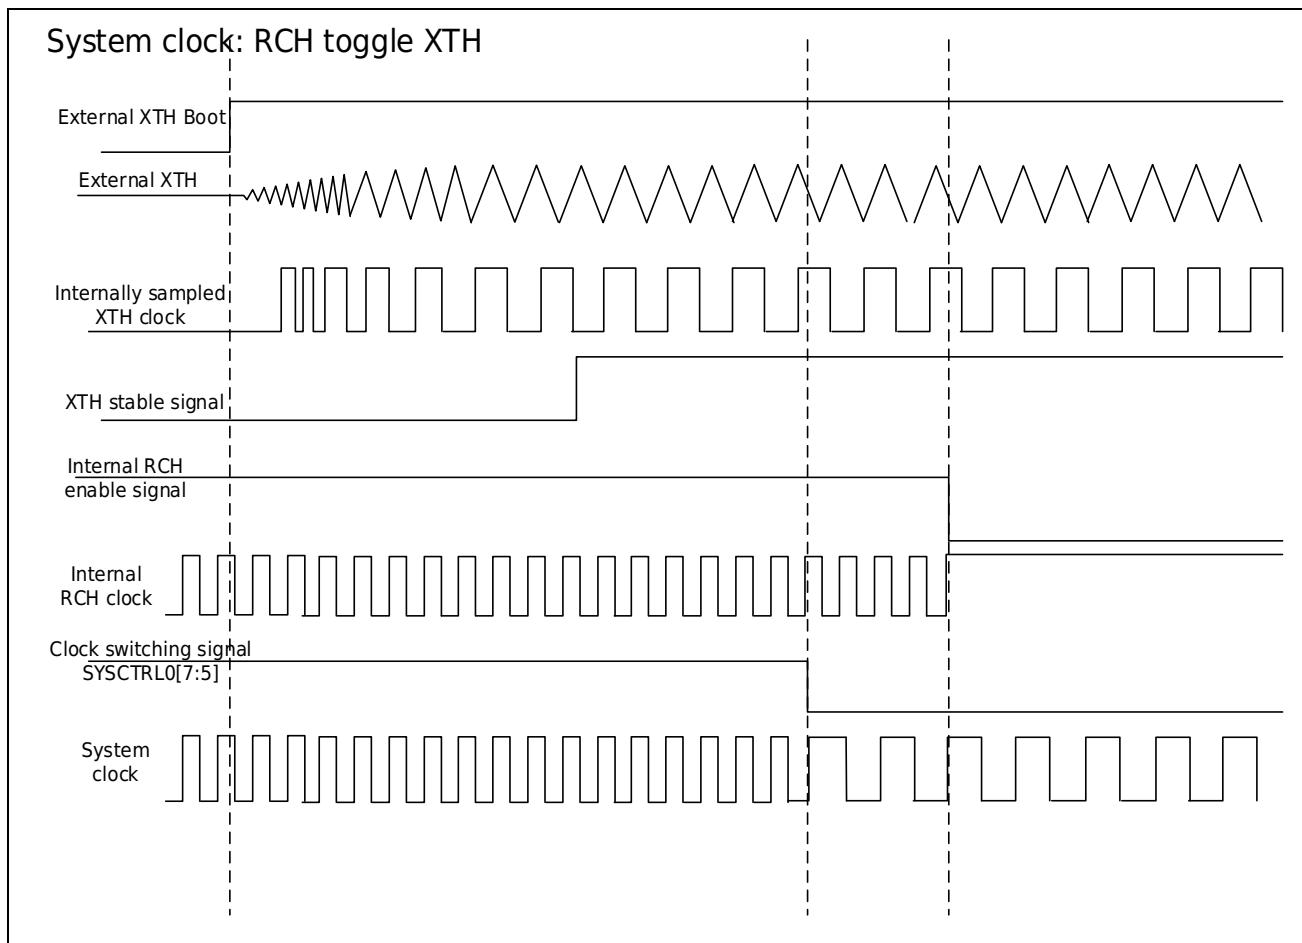

Figure 3-3 Schematic diagram of clock switching

3.3 Clock Calibration Module

This product has a built-in clock calibration circuit. As shown in the figure below, the five sources of the system clock can be calibrated to each other. After selecting the reference clock and the clock to be calibrated, set the register REFCNT value and set cali.start to start the clock calibration circuit. At this time, the two 32-bit counters (increment and decrement) work at the same time. When the decrement counter is equal to 0, cali.finish is set, indicating that the calibration is over. At this time, the software can read the CALCNT value, so that it is easy to get the reference clock and The frequency relationship between the clocks being calibrated.

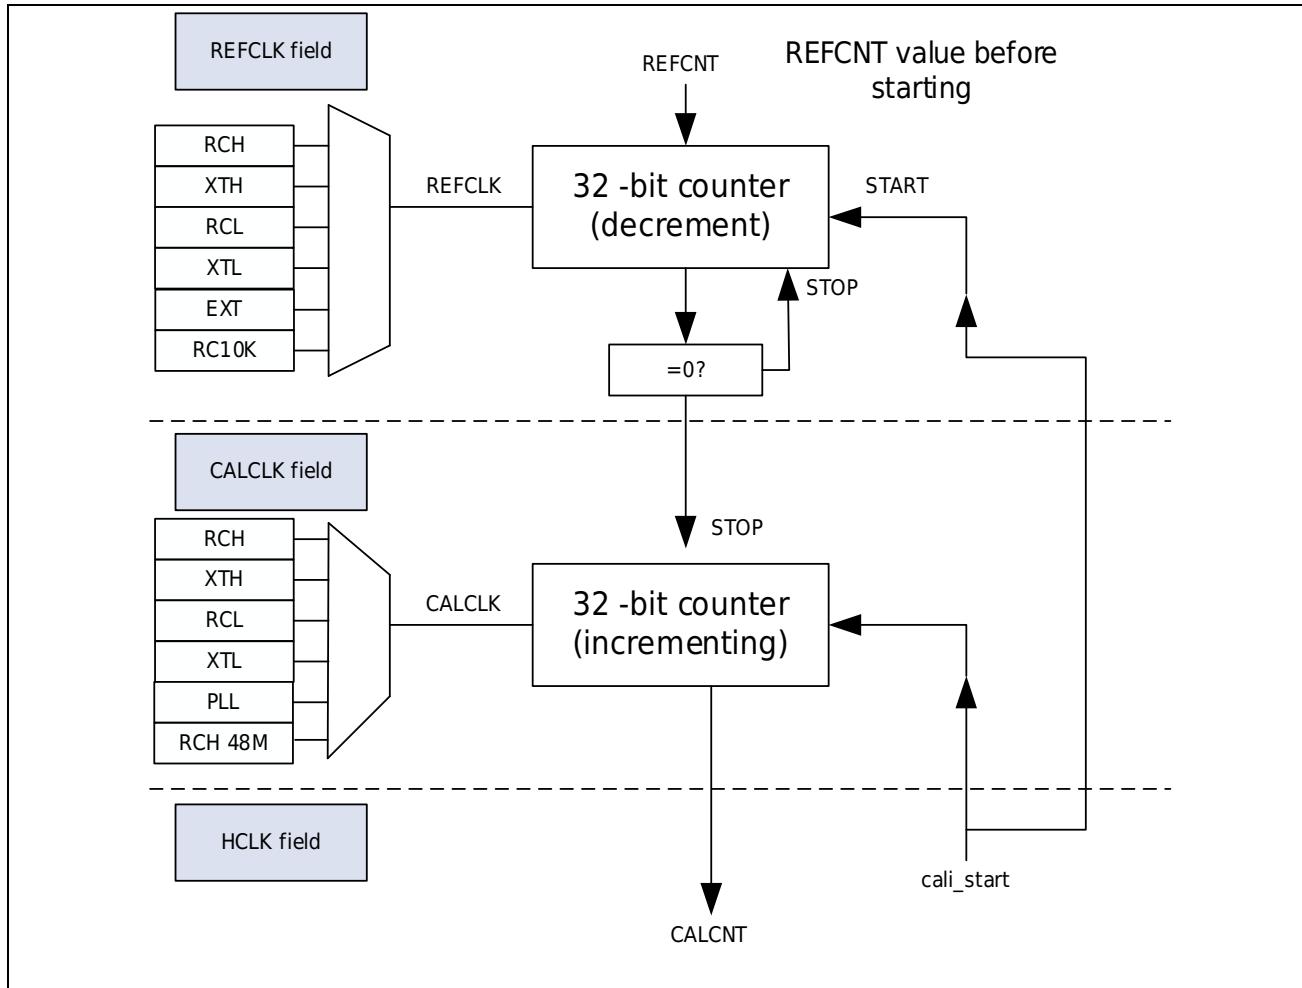

Figure 3-4 Clock Calibration Schematic

3.4 Interrupt Wakeup Control

When the processor executes the WFI instruction to enter the sleep state, it will stop executing instructions. When an interrupt request (higher priority) occurs during sleep and needs to be serviced, the processor is woken up.

The behavior of the processor in the sleep state when receiving an interrupt request is shown in the following table:

PRIMASK status	WFI behavior	Wakeup	ISR execution
0	IRQ Priority > Current Class	Y	Y
0	IRQ Priority \leq Current Level	N	N
1	IRQ Priority > Current Class	Y	N
1	IRQ Priority \leq Current Level	N	N

3.4.1 Enable the NVIC corresponding to the module that needs to wake up the processor

1. Enable the NVIC corresponding to the module that needs to wake up the processor
2. Enable the interrupt corresponding to the module that needs to wake up the processor
3. Set SCB->SCR.SLEEPDEEP to 1
4. Execute WFI instruction to enter deep sleep mode
5. The system enters the deep sleep mode and waits for the interrupt to wake up, and executes the interrupt service program after waking up

Routine:

```
SCB->SCR |= 0x00000004u;
while(1)
{
    __asm__("WFI");
}
```

3.4.2 Method not to execute interrupt service routine after wake-up from deep-sleep mode

1. Enable the NVIC corresponding to the module that needs to wake up the processor
2. Enable the interrupt corresponding to the module that needs to wake up the processor
3. Set PRIMASK to 1
4. Set SCB->SCR.SLEEPDEEP to 1
5. Execute WFI instruction to enter deep sleep mode
6. The system enters the deep sleep mode and waits for the interrupt to wake up, and executes the next instruction after waking up
7. Clear interrupt flag, clear interrupt pending status
8. Execute user-defined actions

Routine:

```
__asm__("CPSID I"); //Set PRIMASK
SCB->SCR |= 0x00000004u;
while(1)
{
    __asm__("WFI");
    MOP_TIMx->ICLR = 0x00;           //Clear Int Flag
    NVIC_ClearPendingIRQ(TIMERLP IRQn); //Clear Pending Flag
    ... // perform user-defined operations
}
```

3.4.3 Using exit hibernation feature

Exiting hibernation (sleep-on-exit) is ideal for interrupt-driven applications. When this feature is enabled, the processor enters sleep mode whenever exception handling is complete and returns to thread mode. With the exit-from-sleep feature, the processor can be in sleep mode as much as possible.

Cortex-M0 uses the exit dormancy feature to enter dormancy. This situation is similar to the effect of executing WFI immediately after executing an abnormal exit. However, in order to avoid the need to push the stack when entering an exception next time, the processor will not perform the process of popping the stack.

1. Enable the NVIC corresponding to the module that needs to wake up the processor
2. Enable the interrupt corresponding to the module that needs to wake up the processor
3. Set SCB->SCR.SLEEPDEEP to 1
4. Set SCB->SCR.SLEEPONEXIT to 1
5. Execute WFI instruction to enter deep sleep mode
6. The system enters the deep sleep mode and waits for the interrupt to wake up, and executes the interrupt service subroutine after waking up
7. Automatically enters sleep mode when exiting interrupt service

Routine:

```
SCB->SCR |= 0x00000004u;
SCB->SCR |= 0x00000002u;
while(1)
{
    __asm("WFI");
}
```

3.5 Register

Base address 0x40002000

Table 3-1 System Control Register

Register	Offset address	Description
SYSCTRL0	0x000	System Control Register 0
SYSCTRL1	0x004	System Control Register 1
SYSCTRL2	0x008	System Control Register 2
RCH_CR	0x00C	RCH Control Register

4 Reset Controller (RESET)

4.1 Reset Controller Introduction

This product has 7 reset signal sources, each reset signal can make the CPU run again, most of the registers will be reset to the reset value, and the program will start to execute from the reset vector.

- Digital area power-on power-off reset POR
- External Reset PAD, low level is reset signal
- WDT reset
- PCA reset
- LVD low voltage reset
- Cortex-M0+ SYSRESETREQ software reset
- Cortex-M0+ LOCKUP hardware reset

Each reset source is indicated by a corresponding reset flag. Reset flags are set by hardware and need to be cleared by user software. When the chip is reset, if `Reset_flag`.POR15V or `Reset_flag`.POR5V is 1, it is a power-on reset. The user program should clear the register `Reset_flag` to 0 during power-on reset, and then the reset source can be judged by the relevant bits of `Reset_flag` at the next reset.

The figure below describes the reset sources for each area.

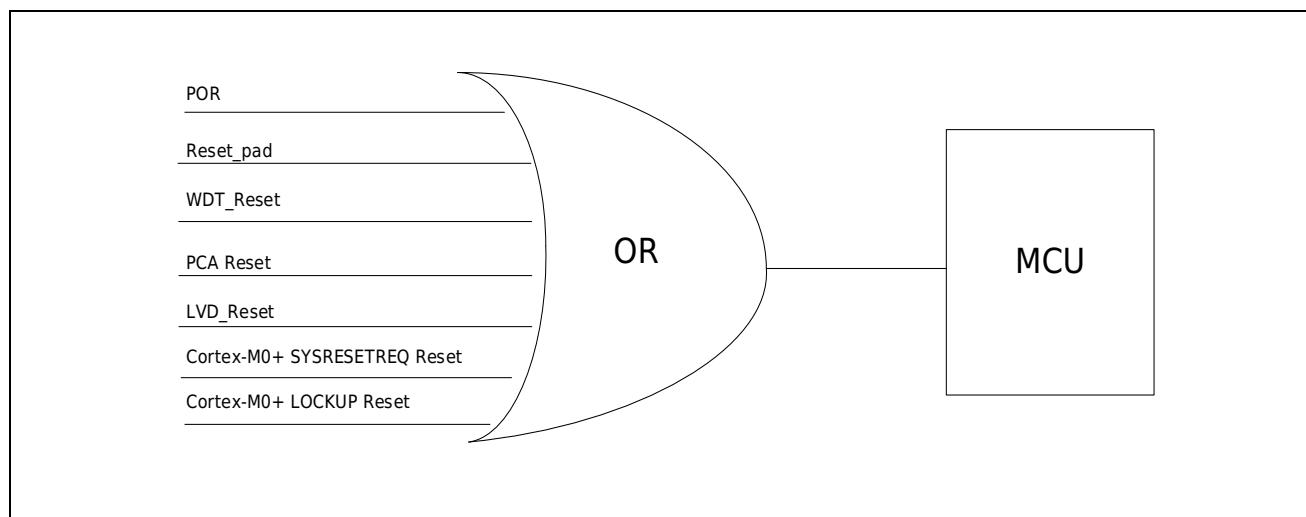

Figure 4-1 Reset Source Schematic

4.1.1 Power-on and power-off reset POR

This product has two power supply areas: VCC area and VCAP area. All analog modules and IO work in the VCC area; other modules work in the VCAP area.

When the VCC area is powered on, when the VCC voltage is lower than the POR threshold voltage (typically 1.65V), a POR5V signal will be generated; when the VCC area is powered off, when the VCC voltage is lower than the BOR threshold voltage (typically 1.5V), will generate POR5V signal.

When the VCAP area is powered on, when the VCAP voltage is lower than the POR threshold voltage, a POR15V signal will be generated; when the VCAP area is powered off, when the VCAP voltage is lower than the BOR threshold voltage, a POR15V signal will be generated.

Both the POR5V signal and the POR15V signal will reset the registers of the chip to the initialization state.

4.1.2 External reset pin reset

A system reset is generated when the external reset pin detects a low level. The reset pin has a built-in pull-up resistor and integrates a glitch filter circuit. The glitch filter circuit will filter the glitch signal less than 20us (typical value), therefore, the low level signal added to the reset pin must be greater than 20us, in order to ensure reliable reset of the chip.

4.1.3 WDT reset

Watchdog reset, please refer to chapter WDT.

4.1.4 PCA reset

PCA reset, please refer to the chapter PCA.

4.1.5 LVD low voltage reset

LVD reset, please refer to chapter LVD.

4.1.6 Cortex-M0+ SYSRESETREQ reset

Cortex-M0+ software reset

4.1.7 Cortex-M0+ LOCKUP reset

When Cortex-M0+ encounters a serious exception, it will stop its PC pointer at the current address, lock itself, and reset the entire CORE area after a few clock cycle delays.

4.2 Register

4.2.1 Reset flag register (RESET_FLAG)

Reset value: 00000000_00000000_00000000_xxxxxx11b

5 Interrupt Controller (NVIC)

5.1 Overview

The Cortex-M0+ processor has a built-in nested vectored interrupt controller (NVIC), which supports up to 32 interrupt request (IRQ) inputs and 1 non-maskable interrupt (NMI) input (not used in this product system). In addition, the processor supports several internal exceptions.

Each exception source has a separate exception number, each exception type has a corresponding priority, some exceptions have a fixed priority, while others are programmable. The details are shown in the following table:

Table 5-1 Cortex-M0+ processor interrupt overview

Exception number	Exception type	Priority	Description
1	Reduction	-3 (highest)	Reduction
2	NMI	-2	Non-maskable interrupt (not used in this system)
3	Hardware error	-1	Error handling exception
4-10	Keep	NA	...
11	SVC	Programmable	Invoke the hypervisor through the SVC command
12-13	Keep	NA	...
14	PendSV	Programmable	Suspendable requests for system services
15	SysTick	Programmable	SysTick timer
16	Interrupt #0	Programmable	External Interrupt #0
17	Interrupt #1	Programmable	External Interrupt #1
...
47	Interrupt #31	Programmable	External Interrupt #31

This chapter only introduces the 32 external interrupt requests of the processor (interrupt #0 to interrupt #31) in detail, and the specific situation of the internal exception of the processor can refer to other related documents. At the same time, this chapter only discusses the interrupt handling mechanism of the NVIC in the processor core, and the interrupt generation mechanism of the peripheral module itself is not discussed here.

5.2 Interrupt priority

Each external interrupt corresponds to a priority register, each priority is 2 bits wide, and uses the highest two bits of the interrupt priority register, and each register occupies 1 byte (8 bits). Under this setting, the available priorities are 0x00 (highest), 0x40, 0x80 and 0xc0 (lowest).

Bit7	Bit6	Bit5	Bit4	Bit3	Bit2	Bit1	Bit0
Used	Not used, read as 0						

Figure 5-1 Only the upper two bits of the priority register are used

Preemption occurs when the processor is already running another interrupt handler and the new interrupt has a higher priority than the one currently being executed. The running interrupt processing will be suspended and the new interrupt will be executed instead. This process is usually called interrupt nesting. After the new interrupt is executed, the previous interrupt processing will continue and return to the program thread after it finishes.

If the processor is running another interrupt handler with the same or higher priority, the new interrupt will wait and enter the pending state. Pending interrupts will wait until the current interrupt level changes, for example, after the currently running interrupt handler finishes returning, the current priority is lowered to be lower than the pending interrupt.

If two interrupts occur at the same time and they have the same priority, the interrupt with the lower interrupt number will be executed first. For example, if interrupt #0 and interrupt #1 are enabled and have the same priority, when they are triggered at the same time, interrupt #0 will be executed first.

5.3 Interrupt digraph

When the Cortex-M0+ processor processes an interrupt service request, it needs to first determine the starting address of the exception handling. The required information is called a vector table, as shown in Figure 5-2. The vector table is stored at the beginning of the memory space and contains the exception (interrupt) vectors of the exceptions (interrupts) available in the system, as well as the initial value of the main stack pointer (MSP).

Memory address	Exception number
0x0000004C	19
0x00000048	18
0x00000044	17
0x00000040	16
0x0000003C	15
0x00000038	14
0x00000034	13
0x00000030	12
0x0000002C	11
0x00000028	10
0x00000024	9
0x00000020	8
0x0000001C	7
0x00000018	6
0x00000014	5
0x00000010	4
0x0000000C	3
0x00000008	2
0x00000004	1
0x00000000	0
	MSP Initial value

Figure 5-2 Interrupt Vector Table

Among them, the storage order of the interrupt vector is consistent with the interrupt number. Since each vector is 1 word (4 bytes), the address of the interrupt vector is the interrupt number multiplied by 4, and each interrupt vector is the starting address of the interrupt processing.

5.4 Interrupt Input and Suspend Behavior

NVIC module of the Cortex-M0+ processor, each interrupt input corresponds to a pending status register, and each register has only 1 bit, which is used to save the interrupt request, regardless of whether the request has been confirmed. When the processor starts servicing the interrupt, the hardware will automatically clear the pending status bit.

The peripherals of this system use level-triggered interrupt output. When an interrupt event occurs, the interrupt signal will be confirmed because the peripheral is connected to the NVIC. This signal remains high until the processor executes the interrupt service and clears the peripheral's interrupt signal. Inside the NVIC, when an interrupt is detected, the pending status of the interrupt will be set, and when the processor receives the interrupt and starts executing the interrupt service routine, the pending status will be cleared. The process is shown in Figure 5-3:

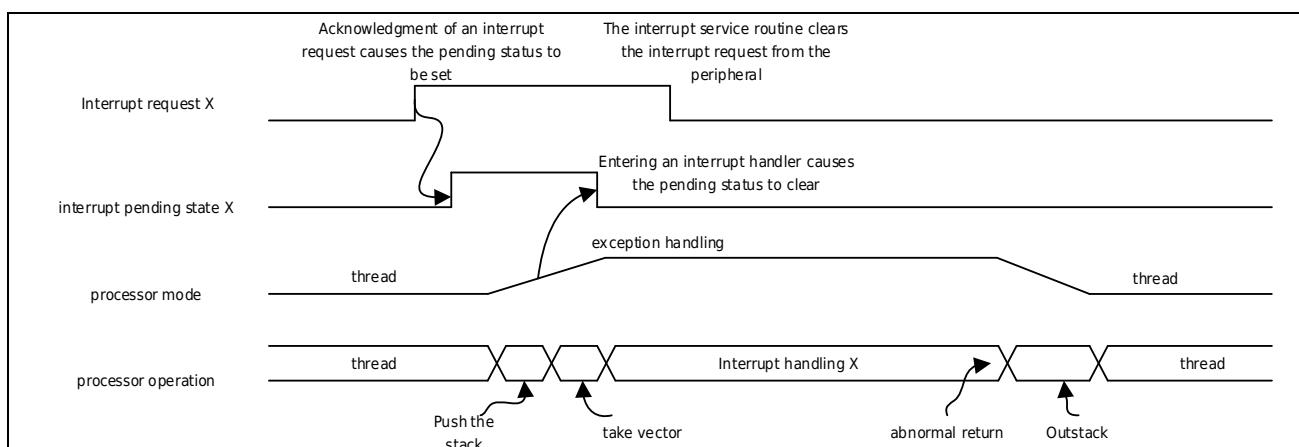

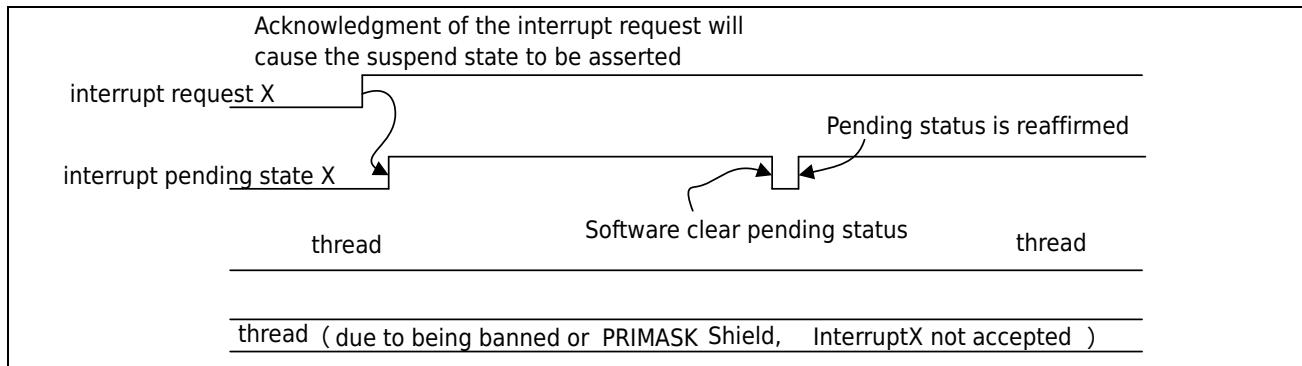

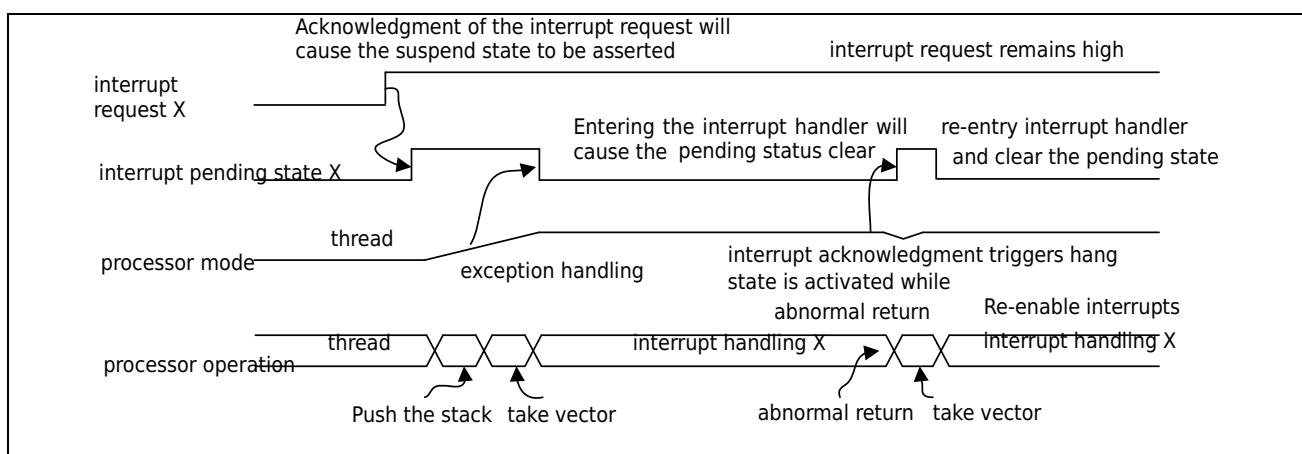

Figure 5-3 Interrupt active and pending states

If the interrupt request is not executed immediately and is cleared by software before being acknowledged, the processor ignores the request and does not perform interrupt processing. The interrupt pending status can be cleared by writing to the NVIC_ICPR register, which is useful when setting up a peripheral that may have generated an interrupt request before setting it.

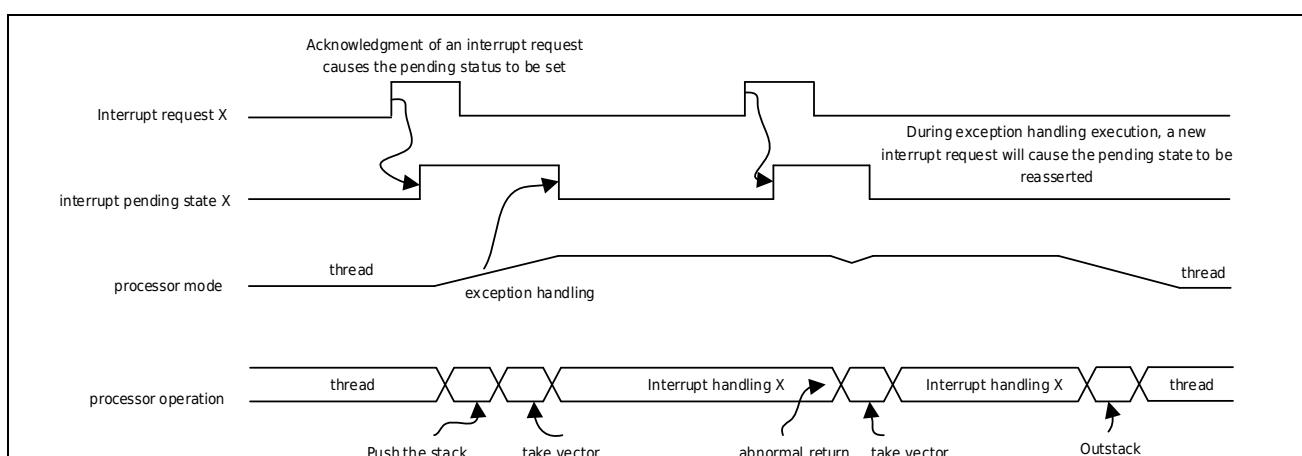

If the peripheral is still holding an interrupt request when software clears the pending state, the pending state is also generated immediately. The process is shown in Figure 5-4:

**Figure 5-4 Interrupt pending status is cleared and then reaffirmed**

If the interrupt request generated by the peripheral is not cleared when the exception is handled, the suspended state will be activated again after the exception returns, so that the interrupt service routine will be executed again. The process is shown in Figure 5-5:

**Figure 5-5 When the interrupt exits, if the interrupt request remains high, it will cause the interrupt processing to be executed again**

If a peripheral interrupt request is generated during the execution of the terminal service program, the request will be regarded as a new interrupt request, and after this interrupt exits, the interrupt service program will be executed again. The process is shown in Figure 5-6:

**Figure 5-6 Interrupt pending interrupts generated during interrupt processing can also be acknowledged**

5.5 Interrupt wait

Typically, the interrupt latency of the NVIC is 16 cycles. This wait time starts from the processor clock cycle when the interrupt is acknowledged, and ends when the interrupt handler starts executing. Computing interrupt waiting requires the following prerequisites:

- The interrupt is enabled and not masked by PRIMASK or other exception handling in progress.
- The memory system does not have any wait states. Bus transfers are used for interrupt processing, stack push, vector fetches, or instruction fetches at the start of interrupt processing. If the memory system needs to wait, the wait states generated when bus transfers occur may delay interrupts.

The following situations may cause different interrupt waits:

- The end of the interrupt is chained. If another interrupt request is generated when the interrupt returns, the processor will skip the process of popping and pushing the stack, thus reducing the interrupt waiting time.
- Delayed arrival. If an interrupt occurs, another low-priority interrupt is being pushed to the stack. Due to the existence of the delayed arrival mechanism, the high-priority interrupt will be executed first, which will also reduce the waiting time of the high-priority interrupt.

5.6 Interrupt source

Because the NVIC of the Cortex-M0+ processor supports up to 32 external interrupts, and in this system, there are more than 32 external interrupt sources, so some external interrupts are multiplexed on the same NVIC interrupt input, where NMI (non-maskable interrupt) and did not use. all external interrupt sources of this system and NVIC interrupt input is shown in the following table:

Table 5-2 Correspondence between external interrupt and NVIC interrupt input

NVIC interrupt input	External interrupt source	Active mode	Sleep mode	DeepSleep mode
Interrupt #0	PORTA	✓	✓	✓
Interrupt #1	PORTB	✓	✓	✓

Interrupt #28	CAN	✓	✓	
Interrupt #29	-			
Interrupt #30	FLASH/RAM	✓	✓	-
Interrupt #31	CLKTRIM/CTS	✓	✓	✓

Note:

- Because some module interrupts are reused for the same IRQ interrupt source, when the CPU enters the interrupt operation, it must first determine which module generated the interrupt, and then perform the corresponding interrupt operation.

5.7 Interrupt structure diagram

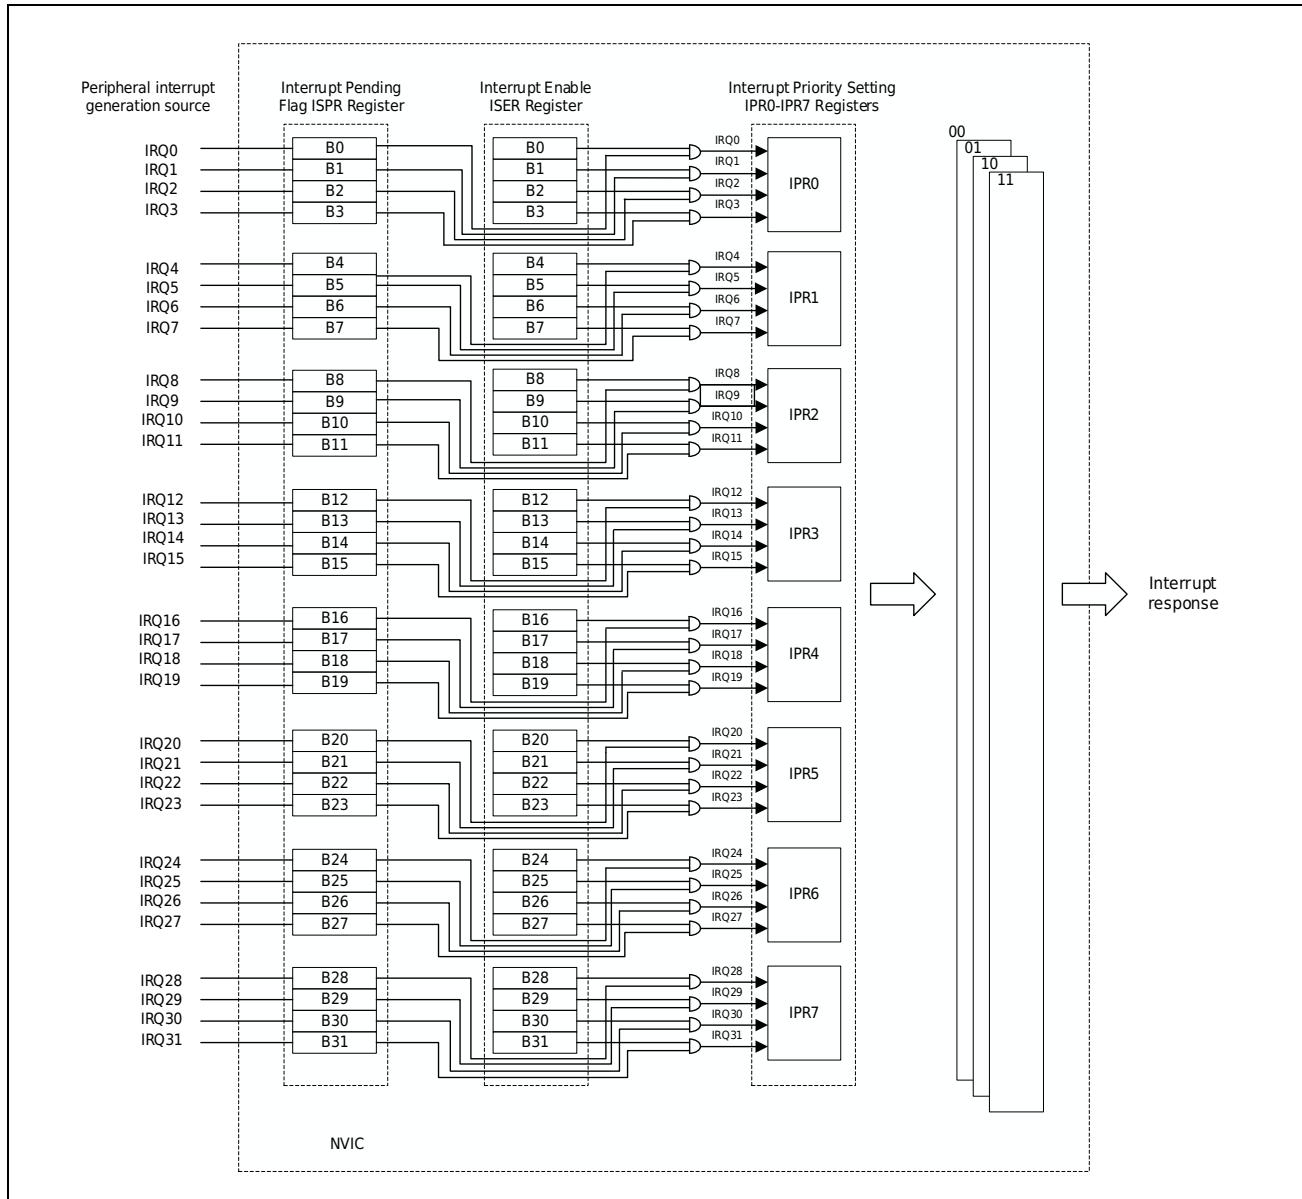

Figure 5-7 Interrupt Structure Diagram

The interrupt structure block diagram of this system is shown in Figure 5-7. A few points to note:

- The respective interrupt enables of the peripheral interrupt sources are not marked in the figure, and only the logic block diagram of the interrupt signal after the peripheral interrupt is generated is included here.
- IRQ has more than one peripheral interrupt input multiplexing, and the interrupt flag bits of these peripherals must be read separately to determine which peripheral interrupt it is.
- If the peripheral interrupt source has a high level, regardless of whether the NVIC interrupt enable register SCS_SETENA is set or not, the interrupt pending register SCS_SEPEND will be set, indicating that the corresponding peripheral interrupt source has an interrupt.

- Only when the interrupt enable register NVIC_ISER is set, the corresponding interrupt IRQ will respond to the processor and execute the corresponding interrupt program.
- In the interrupt program, the high-level interrupt signal of the peripheral interrupt source must be cleared, and the interrupt pending register NVIC_ISPR is automatically cleared by the hardware.
- The interrupt priority registers NVIC_IPR0-NVIC_IPR7 set the priority of 32 interrupt sources, 00 has the highest priority and 11 has the lowest priority. When the priority is the same, the priority is determined by the interrupt number, and the smaller the number, the higher the priority.

5.8 Register

Base address: 0xE000 E000

PRIMASK RW															

Bit	Symbol	Description
31:1	Reserved	
0	PRIMASK	When set, all interrupts except NMI and hardware error exceptions will be masked After clearing, all exceptions and interrupts will not be masked The special register needs to be accessed through MSR and MRS special register operation instructions, and can also be accessed by changing the processor state instruction CPS. When dealing with time-sensitive applications, it is necessary to manipulate the PRIMASK register.

5.9 Basic operation of the software

5.9.1 External interrupt enable

Each peripheral module has its own interrupt enable register. When an interrupt operation is required, the peripheral's own interrupt enable must be enabled first. The operation of this enable bit is not discussed in this chapter, please refer to the respective chapter descriptions of the peripheral modules.

5.9.2 NVIC interrupt enable and clear enable

The Cortex-M0+ processor supports up to 32 interrupt sources, and each interrupt source corresponds to an interrupt enable bit and a clear enable bit. In this way, there are 32-bit interrupt enable register NVIC_ISER and 32-bit clear enable register NVIC_ICER. If you want to enable an interrupt, set the corresponding bit of the NVIC_ISER register to 1. If you want to clear an interrupt, set the corresponding bit in the NVIC_ICER register to 1.

Note that the interrupt enable mentioned here is only for the processor NVIC. Whether the interrupt of each peripheral is generated or not is determined by the interrupt control register of the peripheral, and has nothing to do with NVIC_ISER and NVIC_ICER.

5.9.3 NVIC interrupt pending and clear pending

If an interrupt occurs but cannot be handled immediately, the interrupt request will be pending. The pending state is kept in a register and will remain valid as long as the processor's current priority has not been lowered enough to handle the pending request and the pending state has not been cleared manually.

When the processor starts to enter the interrupt service, the hardware will automatically cause the clearing of the suspended state.

You can access or modify the interrupt pending status by manipulating the interrupt setting pending NVIC_ISPR and interrupt clearing pending NVIC_ICPR registers. The Interrupt Pending Status Register allows software to trigger interrupts.

5.9.4 NVIC interrupt priority

Setting the NVIC_IPR0-NVIC_IPR7 registers determines the priority of SCS_IRQ0-SCS_IRQ32. The programming of the interrupt priority register should be done before the interrupt is enabled, which is usually done at the beginning of the program. Changing the interrupt priority after the interrupt is enabled should be avoided, the result of this situation is unpredictable and is not supported by the Cortex-M0+ processor.

5.9.5 NVIC interrupt mask

Some time-sensitive applications need to disable all interrupts in a short period of time, which can be realized by using the interrupt mask register SCS_PRIMASK. Only 1 bit of the special register SCS_PRIMASK is valid, and it defaults to 0 after reset. When this register is 0, all interrupts and exceptions are enabled; when set to 1, only NMI (not supported by this system) and hardware error exceptions are enabled. In fact, when SCS_PRIMASK is set to 1, the current priority of the processor is reduced to 0 (the highest priority of the summable value).

SCS_PRIMASK register can be programmed in a variety of ways. Using assembly language, the MSR instruction can be used to set and clear the SCS_PRIMASK register. If using C language and CMSIS device driver library, users can use the following functions to set and clear PRIMASK.

```
void __enable_irq(void); // Clear PRIMASK  
void __disable_irq(void); // Set PRIMASK
```

6 Port Controller (GPIO)

6.1 Introduction to Port Controllers

This series has 86 digital general-purpose input and output ports PA[15:0], PB[15:0], PC[15:0], PD[15:0], PE[15:0], PF[11:0], PF[7:0]. All unpackaged GPIOs should also be configured as inputs with pull-ups enabled.

The input and output signals of the analog module ADC/VC/LVD, the input and output signals of each functional module (such as SPI, UART, I2C, Timer, etc.) and digital general-purpose input and output ports are multiplexed.

Each port can be configured as internal pull-up (pull up) / pull-down (pull down) input, high-impedance input (floating input), push-pull output (CMOS output), open drain output (open drain output), two levels drive capability output. "1" and "0" cannot be output, and the result of reading the port input value register by the CPU is "0".

When each digital port is configured as an input, it can provide an external interrupt. The interrupt type can be configured as high-level trigger, low-level trigger, rising edge trigger, and falling edge trigger. Query the interrupt flag bit of Px_STAT [n] You can know the corresponding interrupt trigger port. In addition, each digital port interrupt can wake up the chip from sleep mode / deep sleep mode to active mode.

After the chip is reset, the port is a high-impedance input (floating input), the purpose is to prevent abnormal actions on external devices when the chip is abnormally reset. However, in order to avoid the leakage caused by high-impedance input, the user should configure the port accordingly after the chip is started (configured as internal pull-up/ pull -down input or output).

6.2 Port Controller Main Features

The port controller supports the following features:

- Port input value / output value register supports FAST IO/AHB bus read and write
- Other registers support AHB bus interface read and write
- Analog function pins / digital common pins / digital function pins are multiplexed
- Support pull-up / pull-down / two-speed drive / open-drain output function selection
- Support interrupt in working mode/sleep mode/deep sleep mode
- Support high level / low level / rising edge / falling edge trigger interrupt
- Support bit set, bit clear, bit clear function

Note: For the introduction of FAST IO, please refer to ARM Cortex-M0+_IntegrationAndImplementationManual.pdf.

6.3 Port Controller Functional Description

6.3.1 Port configuration function

Each port can be configured as an analog port or a digital port through the configuration register (PxADS) according to system requirements. When PxADS is '1', the port is configured as an analog port, and when PxADS is '0', the port is configured as a digital port.

The port circuit structure is shown in the figure below:

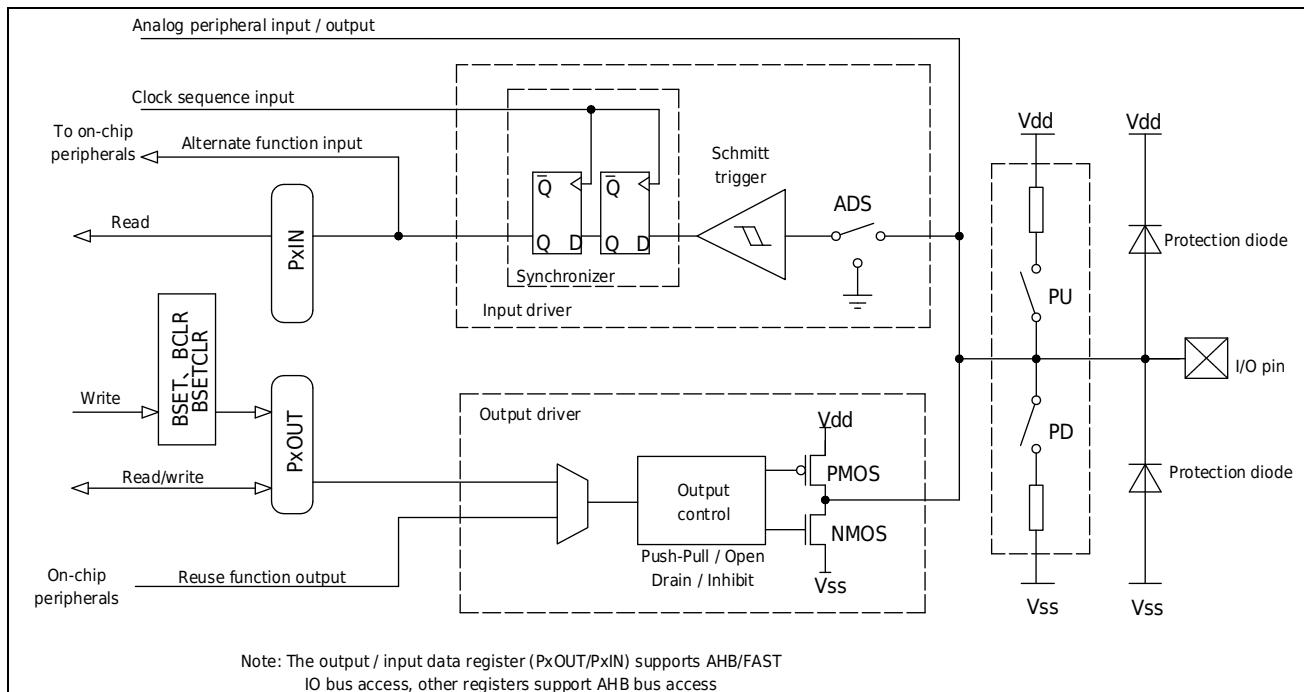

Figure 6-1 Port Circuit Diagram

When the port is configured as a digital port, it can accept digital general-purpose input and output signals (set the Px_SEL register to '0'), or accept the input and output signals of various functional modules (such as SPI, UART, I2C, Timer, etc.) through the configuration register Px_SEL. For details, refer to the port digital multiplexing function module.

You can also configure the corresponding registers to achieve the following features:

1) Internal pull-up (PxPU) / pull-down (PxPD)

The pull-up register (PxPU) and the pull-down register (PxPD) correspond to the port pull-up enable and port pull-down enable respectively. When the corresponding bit is '1', set the corresponding bit pin pull-up / pull-down enable to '0', disable the pull-up / pull-down of the corresponding bit pin.

2) Two-speed drive output (PxDR)

The driving ability can be changed through the PxDR register. When PxDR is '1', it is low driving ability, and when PxDR is '0', it is high driving ability.

3) Open Drain Output (PxOD)

Set the pin output state through the PxOD register. When PxOD is '1', the port open-drain output is enabled, and when it is '0', the port push-pull output is enabled. When the open-drain pin is not connected to an external pull-up resistor, it can only output low level. If it needs to output high level at the same time, a pull-up resistor is required.

4) Direction selection (PxDIR)

Used to set the direction of the port pin. PxDIR is '0', the port is output, and when PxDIR is '1', the port is input.

5) Input level status (PxIN)

The synchronized pin level can be obtained by reading the PxIN register. When PxIN is '1', it is high level, and when PxIN is '0', it is low level. Accessible via AHB/FAST IO bus

6) Output high- and low-level selection (PxOUT)

When the port pin is configured as an output, if PxOUT is '1', the port pin output is high level, if PxOUT is '0', the output is low level. Accessible via AHB/FAST IO bus

7) Bit set (PxBSSET), bit cleared (PxBCCLR), bit set cleared (PxBSSETCLR)

Bit setting and bit clearing are applicable to setting the bit that the user wants to change to obtain the corresponding value without changing the value of other bits. When a bit is set, the corresponding value is set to '1', and when a bit is cleared, the corresponding value is set to '0'.

Note:

- The above features are invalid when configured as an analog port.

The relationship between port status and register configuration is as follows:

Table 6-1 Port State Truth Table

IO state	IO direction	PxAD S	PxDI R	PxOUT	PxIN	PxBSE T	PxBCL R	PxBSETCL R	PxP U	PxP D	PxO D	PxD R	Px_SEL
Simulation	Input/Output	1	W	W	0	W	W	W	W	W	W	W	W
Floating	Input	0	1	W	X	W	W	W	0	0	W	W	0
Drop down	Input	0	1	W	0	W	W	W	0	1	W	W	0
Pull-up	Input	0	1	W	1	W	W	W	1	0	W	W	0
Pull-up	Input	0	1	W	1	W	W	W	1	1	W	W	0
1	Input	0	1	W	1	W	W	W	W	W	W	W	0
0	Input	0	1	W	0	W	W	W	W	W	W	W	0
1	Output	0	0	1	1	0	0	0	W	W	0	W	0
0	Output	0	0	0	0	0	0	0	W	W	0	W	0
1	Output	0	0	W	1	1	0	0	W	W	0	W	0
0	Output	0	0	W	0	0	1	0	W	W	0	W	0
(SET) 1	Output	0	0	W	(SET) 1	0	0	1	W	W	0	W	0
(CLR) 0	Output	0	0	W	(CLR) 0	0	0	1	W	W	0	W	0
0	Output	0	0	0	0	0	0	0	W	W	1	W	0
Z	Output	0	0	1	X	0	0	0	0	0	1	W	0
0	Output	0	0	1	0	0	0	0	0	1	1	W	0
1	Output	0	0	1	1	0	0	0	1	0	1	W	0
1	Output	0	0	1	1	0	0	0	1	1	1	W	0

Note: 0 - Logic low 1 - Logic high W - Whatever 0 or 1 X - unknown state Z - high impedance

6.3.2 Port write

The port input value / output value register (PxIN/PxOUT) supports reading and writing of the AHB bus and the FAST IO bus (controlled by the register GPIO_CTRL2.ahb_sel bit), and only supports reading and writing of the AHB bus for other registers. For these two different buses, the system clock (HCLK) has different processing cycles for these two buses. The following two figures show the fastest timing for two bus port flips:

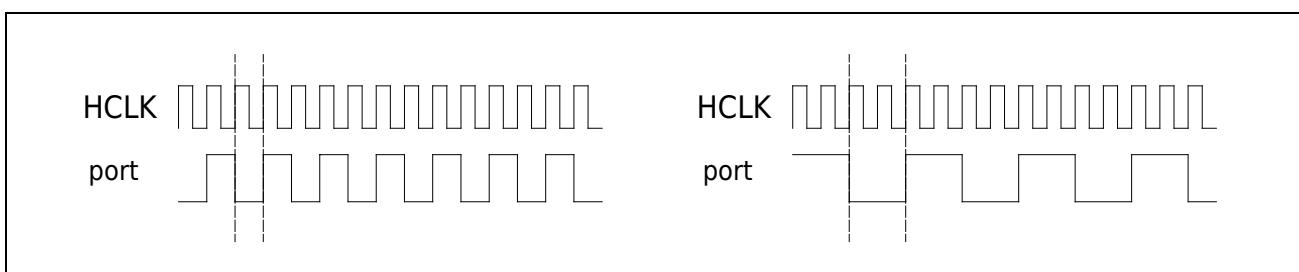

Figure 6-2 AHB/FASTIO bus port changes with system clock

(Left is FASTIO, right is AHB)

For the AHB bus, every two HCLK cycles, the IO flips once, and for the FAST IO bus, every HCLK cycle, the IO flips once.

6.3.3 port read

Each port can get the port pin level by reading the PxIN register. As shown in Figure 6-1, each bit of the PxIN register and its preceding latch form a synchronizer to avoid signal instability caused by pin level changes in a short period of time when the system clock state changes, but also introduces delay. The synchronization diagram for reading port pin data is as follows:

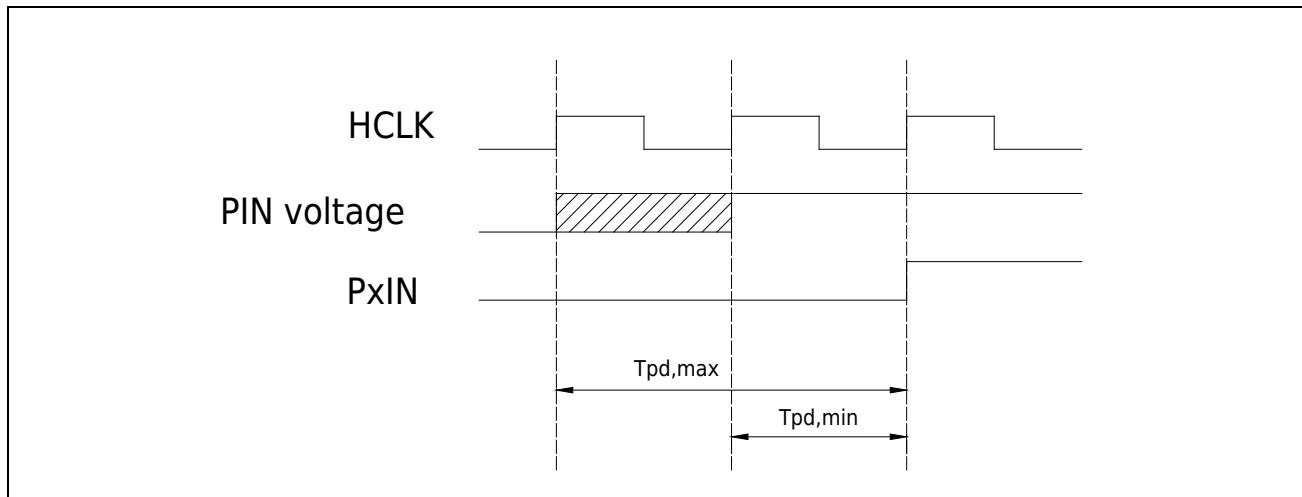

Figure 6-3 Read port pin data synchronization diagram

During the clock period after the rising edge of the system clock, the pin level signal will be latched in the internal register, as shown in the shaded part, after the next rising edge of the system clock, the stable pin level signal can be read. Then, when the system clock rises, the data is latched into the PxIN register. The signal replacement delay T_{pd} is 1-2 system clocks.

Note:

- Handling of unconnected pins:

If there are unconnected pins during use, in order to avoid current consumption caused by pins not having a certain level in other digital input enable modes, it is recommended to assign a certain level to the pin.

6.3.4 Port digital multiplexing function

Port digital multiplexing is one of the main functions of the port controller. Through the configuration register, the port can be flexibly configured as a test and debug port / digital general port / digital function port.

As shown in the table below: The Px_SEL register is used for digital general-purpose port / digital function port switching, and each port can be independently configured as a functional port required by the system. For the configuration information of the debug port, please refer to the relevant chapters.

Table 6-2 Port multiplexing table

6.3.5 Port interrupt function

Each digital general-purpose port can be interrupted by an external signal source. The external signal source can be four types of signals: high level / low level / rising edge / falling edge, and the corresponding interrupt enable registers are high level interrupts. Enable Register (PxHIE)/ Low Level Interrupt Enable Register (PxLIE)/ Rising Edge Interrupt Enable Register (PxRIE)/ Falling Edge Interrupt Enable Register (PxFIE). When an interrupt is triggered, it can be determined which port triggered the interrupt by querying the interrupt status register (Px_STAT), and the corresponding interrupt status flag bit can be cleared by clearing the interrupt clear register (Px_ICLR).

6.4 Port configuration operation flow

6.4.1 Port multiplexing is configured as an analog port operation flow

- a) Set register PxADS[n] to 1

6.4.2 Port multiplexing configured as a digital universal port operation flow

- a) Set register PxADS[n] to 0
- b) Set register Px_SEL to 0
- c) Set the register PxDIR[n] to 1: the port direction is input, and the CPU can read the port status PxIN[n].
- d) Set the register PxDIR[n] to 0: port direction is output
- e) Set the register PxOUT[n] to 1: the port outputs a high level
- f) Set the register PxOUT[n] to 0: port output low level

6.4.3 Port multiplexing configured as a digital function port operation flow

- a) Set register PxADS[n] to 0
- b) Set the register Px_SEL to 1~7 (according to the system requirements, refer to the port multiplexing table)
- c) Set register PxDIR[n] (according to system requirements)
- d) Set registers PxPU[n]/PxPD[n]/PxOD[n] (according to system requirements)

6.4.4 Port multiplexing is configured as a debug test port operation process

Refer to the chapters related to testing and debugging.

6.4.5 Port multiplexing configured as infrared output signal operation process

Ports PA13, PB09, and PC04 can modulate the internal clock signal with a frequency of 38K into infrared signal output.

- a) Set register PAADS[13]/PBADS[9]/PCADS[4] to 0
- b) Set register PA13_SEL = 1/PB09_SEL = 2/PC04_SEL = 3
- c) Set register PADIR[13] = 0/PBDIR[9] = 0/PCDIR[4] = 0: Port direction is output
- d) Set the bit14 of the register GPIO_CTRL1 to select the output polarity of the infrared signal
- e) Set the output of the register PAOUT[13]/PBOUT[9]/PCOUT[4] to control the infrared signal

6.4.6 Port high level interrupt operation flow

- a) Set register PxADS[n] to 0
- b) Set register Px_SEL to 0
- c) Set register PxDIR[n] to 1
- d) Set register Px_HIE[n] to 1

- e) Read the interrupt status register Px_STAT[n] after the interrupt is triggered
- f) Set the register Px_ICLR[n] to 0 to clear the interrupt status register Px_STAT[n]

6.4.7 Port low level interrupt operation flow

- a) Set register PxADS[n] to 0
- b) Set register Px_SEL to 0
- c) Set register PxDIR[n] to 1
- d) Set register Px_LIE[n] to 1
- e) Read the interrupt status register Px_STAT[n] after the interrupt is triggered
- f) Set the register Px_ICLR[n] to 0 to clear the interrupt status register Px_STAT[n]

6.4.8 Port rising edge interrupt operation flow

- a) Set register PxADS[n] to 0
- b) Set register Px_SEL to 0
- c) Set register PxDIR[n] to 1
- d) Set register Px_RIE[n] to 1
- e) Read the interrupt status register Px_STAT[n] after the interrupt is triggered
- f) Set the register Px_ICLR[n] to 0 to clear the interrupt status register Px_STAT[n]

6.4.9 Port falling edge interrupt operation flow

- a) Set register PxADS[n] to 0
- b) Set register Px_SEL to 0
- c) Set register PxDIR[n] to 1
- d) Set register Px_FIE[n] to 1
- e) Read the interrupt status register Px_STAT[n] after the interrupt is triggered
- f) Set the register Px_ICLR[n] to 0 to clear the interrupt status register Px_STAT[n]

6.4.10 Port pull-up enable configuration operation flow

- a) Set register PxPU[n] to 1

6.4.11 Port pull-down enable configuration operation flow

- a) Set register PxPU[n] to 0
- b) Set register PxPD[n] to 1

Note: When PxPU[n] and PxPD[n] are set to 1 at the same time, PxPU[n] has higher priority and PxPD[n] is invalid.

6.4.12 Port Enhancement Driver Configuration Operation Flow

- a) Set register PxDR[n] to 0

6.4.13 Port open-drain output configuration operation flow

- a) Set register PxOD[n] to 1

6.4.14 Port bit setting operation flow

- a) Set register PxBSET[n] to 1

6.4.15 Port bit clearing operation flow

- a) Set register PxBCLR[n] to 1

6.4.16 Operation flow of port bit setting and clearing

- a) Set register PxBSETCLR[n] to 1

6.5.1 Port general register

6.5.1.1 Port Px input and output configuration register (PxDIR) (x = A, B, C, D, E, F)

Address offset:

0x100(PA),0x140(PB),0x180(PC),0x1C0(PD),0x1100(PE),0x1140(PF)

Reset value: 0xffff ffff

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PxDIR[15:0]															
rw															

Bit	Marking	Functional description
31:16	Reserved	Keep
15:0	PxDIR	Port Px input and output configuration register (corresponding to Px15-Px00) 1: configured as input 0: configured as output Note: Each bit corresponds to a port, for example: PxDIR[15] corresponds to port Px15

6.5.1.2 Port Px Input Value Register (PxIN) (x = A, B, C, D, E, F)

Address offset:

0x104(PA),0x144(PB),0x184(PC),0x1C4(PD),0x1104(PE),0x1144(PF)

Reset value: NA

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PxIN[15:0]															
ro															

Bit	Marking	Functional description
31:16	Reserved	Keep
15:0	PxIN	Port Px input value register (corresponding to Px15-Px00) 1: Input is high level 0: Input is low level

6.5.1.3 Port Px output value configuration register (PxOUT) (x = A, B, C, D, E, F)

Address offset:

0x108(PA),0x148(PB),0x188(PC),0x1C8(PD),0x1108(PE),0x1148(PF)

Reset value: NA

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PxOUT[15:0]															
rw															

Bit	Marking	Functional description
31:16	Reserved	Keep
15:0	PxOUT	Port Px output value configuration register (corresponding to Px15-Px00) 1: Output high level If it is configured as an open-drain output, an external pull-up resistor is required to pull it high. 0: Output low level

6.5.1.4 Port Px Digital-to-Analog Configuration Register (PxADS) (x = A, B, C, D, E, F)

Address offset:

0x10C(PA),0x14C(PB),0x18C(PC),0x1CC(PD),0x110C(PE),0x114C(PF)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PxADS[15:0]															
rw															

Bit	Marking	Functional description
31:16	Reserved	Keep
15:0	PxADS	Port Px digital-analog configuration register (corresponding to Px15-Px00) 1: configured as an analog port 0: configured as a digital port

6.5.1.5 Port Px Bit Set Register (PxBSSET) ($x = A, B, C, D, E, F$)

Address offset:

0x110(PA),0x150(PB),0x190(PC),0x1D0(PD),0x1110(PE),0x1150(PF)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

7 I2C bus (I2C)

7.1 Introduction

I2C is a two-wire bidirectional synchronous serial bus, which uses a clock line and a data line to transmit information between two devices connected to the bus, providing a simple and efficient method for data exchange between devices. Each device connected to the bus has a unique address, and any device can be used as both a master and a slave, but only one master is allowed at the same time. I2C standard is a real multi-master bus with a conflict detection mechanism and an arbitration mechanism. It can use the arbitration mechanism to avoid data conflicts and protect data when multiple Masters request control of the bus at the same time.

I2C bus controller can meet various specifications of the I2C bus and support all transmission modes communicating with the I2C bus. The I2C logic can handle byte transfers autonomously. It can keep track of the serial transfer, and there is a status register (I2Cx_STAT) that can reflect the status of the I2C bus controller and the I2C bus.

7.2 Main characteristics

I2C controller supports the following features:

- Support four working modes of master sending/receiving and slave sending/receiving
- Support standard (100Kbps) / fast (400Kbps) / high speed (1Mbps) three working rates
- Support 7-bit addressing function
- Support noise filtering function
- Support broadcast address
- Support interrupt status query function

7.3 protocol description

The I2C bus uses "SCL" (serial clock bus) and "SDA" (serial data bus) to connect devices to transfer information. The Master computer outputs a serial clock signal on the SCL line, and the data is transmitted on the SDA line, and each byte is transmitted (the highest bit MSB starts to be transmitted), followed by an acknowledge bit. One SCL clock pulse transfers one data bit.

7.3.1 Data transmission on the I2C bus

Usually the standard I2C transmission protocol consists of four parts: start (S) or repeated start signal (Sr), slave address and read and write bits, transmission data, and stop signal (P).

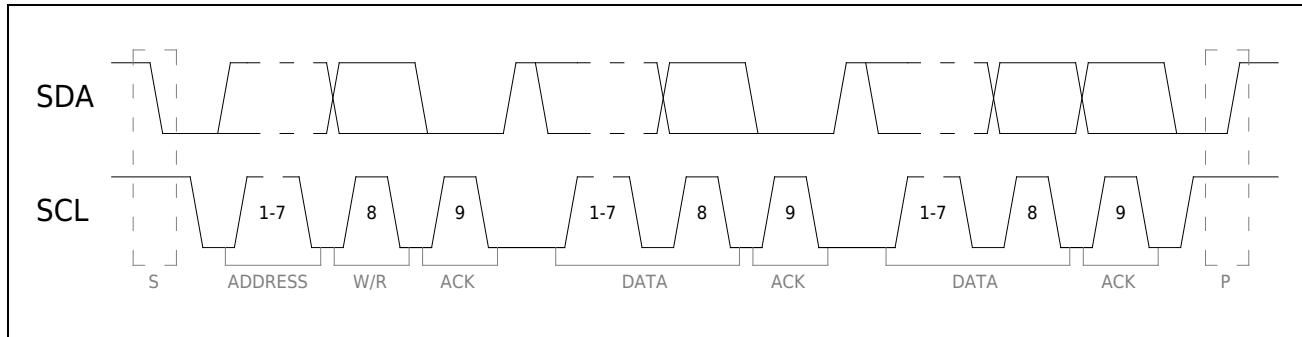

Figure 7-1 I2C transfer protocol

- Start signal, repeat start signal, stop signal
 - When the bus is in an idle state (the SCL and SDA lines are high at the same time), a signal from high to low appears on the SDA line, indicating that a start signal is generated on the bus.
 - A repeated start signal occurs when there is no stop signal between two start signals. This method is used by a master to communicate with another slave or the same slave with a different transfer direction (for example: from writing to the device to reading from the device) without releasing the bus.
 - When the SCL line is high, a low-to-high signal appears on the SDA line, which is defined as a stop signal. The master sends a stop signal to the bus to end the data transfer.

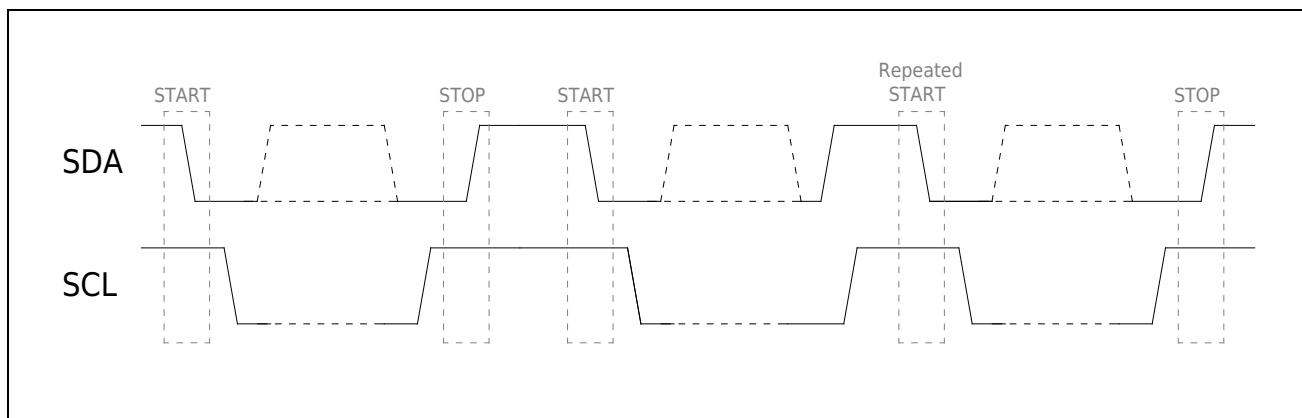

Figure 7-2 START and STOP conditions

- Slave address and read/write bits
 - When the start signal is generated, the Master immediately transmits the first byte of data: 7-bit slave address + read and write bits, the read and write bits control the data transmission direction of the slave (0: write; 1: read). A slave addressed by the master will acknowledge by pulling SDA low on the ninth SCL clock cycle.
- Transfer data
 - During data transfer, one SCL clock pulse transfers one data bit, and the SDA line can only change when SCL is low.

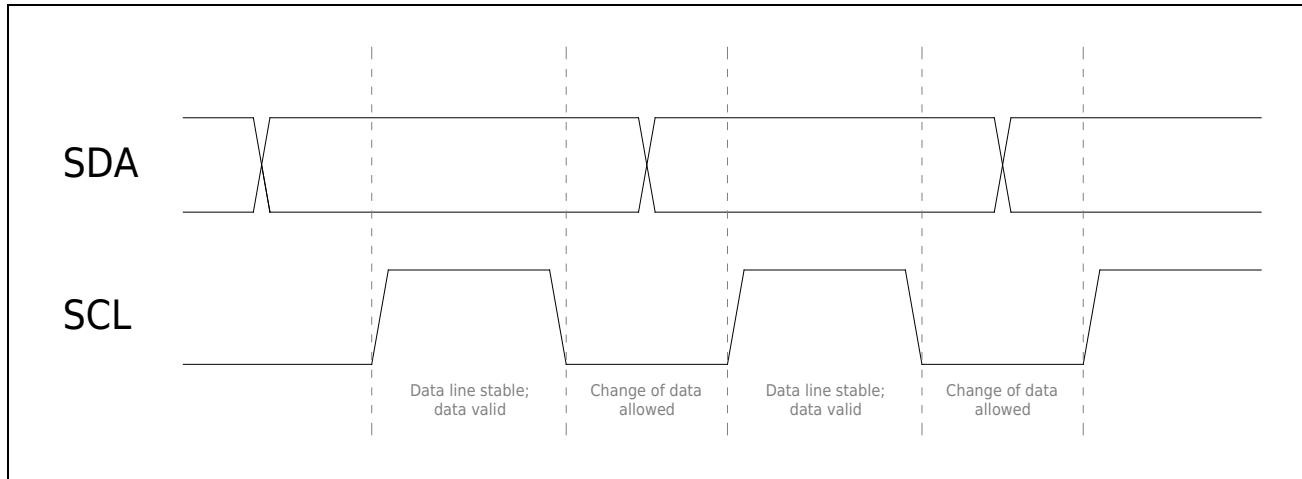

Figure 7-3 Bit transfer on the I2C bus

7.3.2 Acknowledgment on the I2C bus

Each byte transferred is followed by an acknowledge bit. By pulling the SDA line low, the receiver is allowed to echo the transmitter. ACK is a low-level signal. When the clock signal is high, SDA remains low to indicate that the receiving end has successfully received the data from the sending end.

(NACK) is generated on the slave, the Master can generate a stop signal to exit data transmission, or generate a repeated start signal to start a new round of data transmission. When the Master is used as a receiving device, a non-response signal (NACK) occurs, and the slave releases the SDA line, causing the Master to generate a stop signal or a repeated start signal.

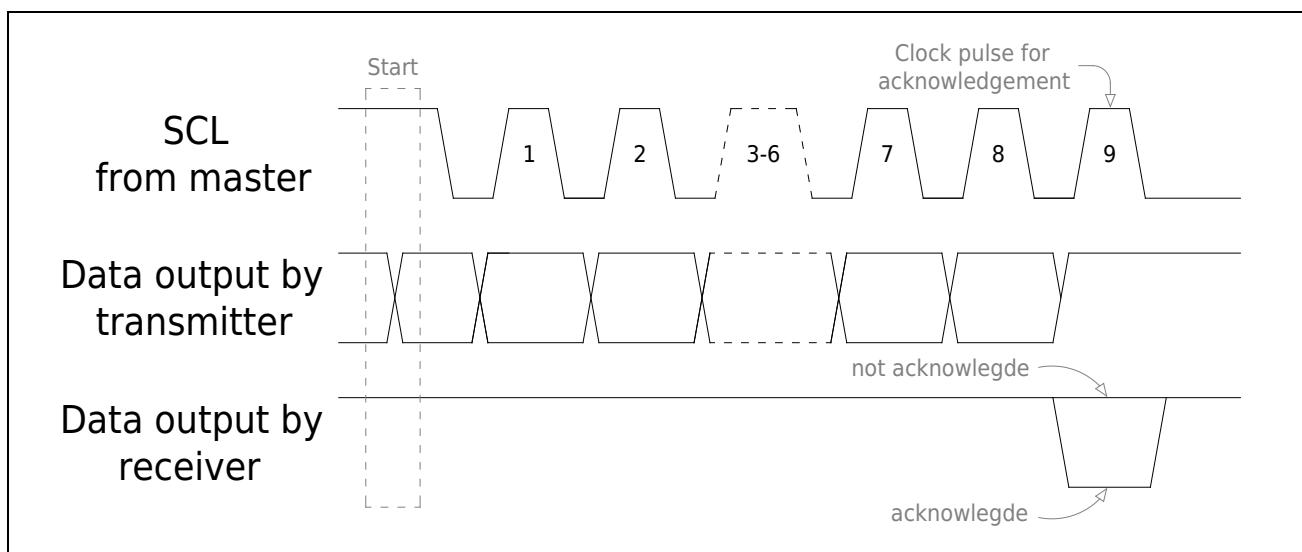

Figure 7-4 Acknowledgment signal on I2C bus

7.3.3 Arbitration on the I2C bus

Arbitration on the I2C bus is divided into two parts: synchronization on the SCL line and arbitration on the SDA line

- Synchronization on the SCL line (clock synchronization)

- Since the I2C bus has the logic function of "AND", as long as one node on the SCL line sends a low level, the bus will show a low level. The bus can only behave as a high level when all nodes are sending a high level. Therefore, the clock low time is determined by the device with the longest clock level period, and the clock high time is determined by the device with the shortest clock high period. Due to the characteristics of I2C, when multiple Masters send clock signals at the same time, a unified clock signal is represented on the bus. If the slave wants the Master to reduce the transmission speed, it can notify the Master by actively pulling SCL low to extend its low level time. When the Master finds that the SCL level is pulled low when preparing for the next transmission, it waits until the slave completes the operation. And release control of the SCL line.
- Arbitration on SDA Online
 - The arbitration on the SDA line is also due to the logical function of the "AND" of the I2C bus. After the master sends data, it decides whether to exit the competition by comparing the data on the bus. The master that loses the arbitration immediately switches to the unaddressed slave state to ensure that it can be addressed by the master that wins the arbitration. A master that loses arbitration continues to output clock pulses (on SCL) until the current serial byte has been sent. This principle can ensure that the I2C bus will not lose data when multiple Masters attempt to control the bus.

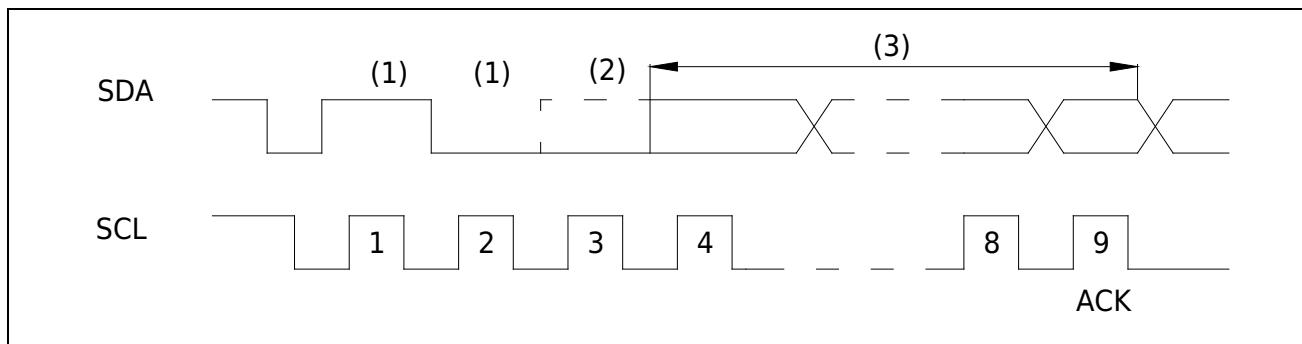

Figure 7-5 Arbitration on the I2C bus

- a) Another device sends serial data;
- b) Another device first negates a logic 1 sent by the I2C master by pulling SDA low (dotted line). Arbitration is lost, I2C enters slave receive mode;
- c) At this time, I2C is in the slave receiving mode, but still generates clock pulses until the current byte is sent. I2C will not generate a clock pulse for the next byte transfer. Once arbitration is won, the data transfer on SDA is initiated by the new master.

7.4 Functional description

The I2C bus uses two wires to transfer information between devices connected to the bus "SCL" (Serial Clock Line) and "SDA" (Serial Data Line). Filtering logic can filter glitches on the data bus to protect data integrity. Since there are only non-directional ports, the I2C component requires the use of open-drain buffers to the pins. Each device connected to the bus can be addressed by a specific address using software. The I2C standard is a true multi-master bus with a collision detection mechanism and an arbitration mechanism. It prevents data collisions when two or more Masters start transmitting data at the same time. I2C bus can be queried in the status register.

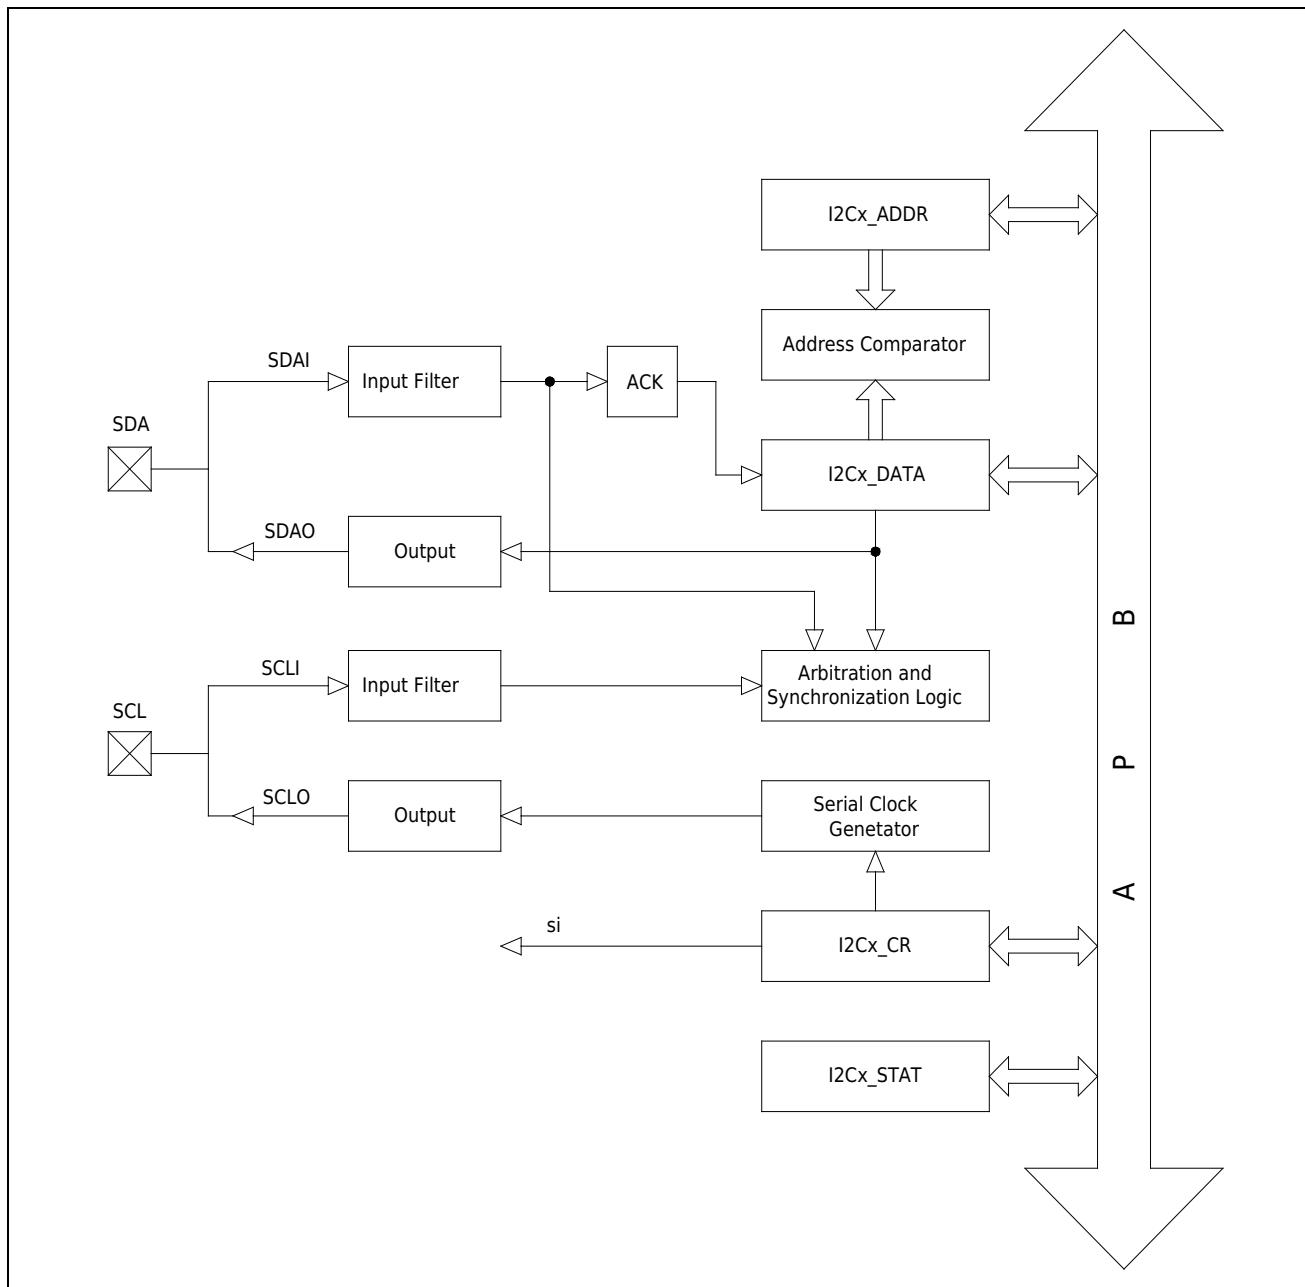

Figure 7-6 I2C function block diagram

7.4.1 Serial clock generator

The serial clock generator uses an 8-bit counter as the baud rate generator. The frequency relationship between the SCL signal and the PCLK signal is $F_{SCL} = F_{PCLK} / 8 / (I2Cx_TM.tm + 1)$, where $I2Cx_TM.tm$ should be greater than 0.

The following table lists the output frequency value of SCL signal when PCLK frequency is combined with $I2Cx_TM.tm$.

Table 7-1 I2C clock signal baud rate

PCLK (KHz)	I2Cx_TM.tm						
	1	2	3	4	5	6	7
1000	62	41	31	25	20	17	15
2000	125	83	62	50	41	35	31
4000	250	166	125	100	83	71	62
6000	375	250	187	150	125	107	93
8000	500	333	250	200	166	142	125
10000	625	416	312	250	208	178	156
12000	750	500	375	300	250	214	187
14000	875	583	437	350	291	250	218
16000	1000	666	500	400	333	285	250

7.4.2 Input filter

The input signal is synchronous with PCLK, and the spike pulse signal lower than the period of PCLK will be filtered out.

When this module is used as the Master, if the value of $I2C_TM$ is less than or equal to 9, $I2C_CR.H1M$ should be set to 1; if the value of $I2C_TM$ is greater than 9, $I2C_CR.H1M$ should be set to 0.

When this module is used as a slave, if the ratio of PCLK to SCL frequency is less than or equal to 30, $I2C_CR.H1M$ should be set to 1; if the ratio of PCLK to SCL frequency is greater than 30, $I2C_CR.H1M$ should be set to 0.

7.4.3 Address comparator

I2C comparator compares its own slave address with the received 7-bit slave address. It can program its own slave address using the "I2Cx_ADDR" register. And it will be compared with the first received 8-bit byte or broadcast address (0x00) according to the "i2cad" bit of the "I2Cx_ADDR" register. If any one is the same, the "si" bit of the "I2Cx_CR" register will be set to 1 and an interrupt request will be generated.

7.4.4 response flag

"aa" flag in the "I2Cx_CR" register is the answer flag. When the "aa" bit is 1, the I2C module responds with an acknowledgement bit after receiving the data, and when the "aa" bit is 0, the I2C module returns a non-acknowledgement bit after receiving the data.

7.4.5 interrupt generator

"si" flag in the "I2Cx_CR" register is an interrupt flag. "si" flag is set to 1 whenever the value of the status register (I2Cx_STAT) changes (except to 0xF8). When an interrupt is generated, the status of the I2C bus can be obtained by querying the status register (I2Cx_STAT) to determine the actual source of the interrupt. In order to proceed to the next step, the "si" flag must be cleared by software.

7.4.6 Operating mode

The I2C component can realize 8-bit bidirectional data transmission, the transmission rate can reach 100Kbps in standard mode, 400Kbps in high-speed mode, and 1Mbps in ultra-high-speed mode, and can work in four modes: Master send mode, Master receiving mode, slave receiving mode, slave sending mode. There is also a special mode, general call mode, which operates in a similar way to slave receive mode.

■ Host send mode

The Master sends multiple bytes to the slave, and the Master generates a clock, so it is necessary to fill in the set value in I2Cx_TM. I2Cx_CR.sta needs to be set to 1 in master send mode. When the bus is free, the master initiates a start bit START. I2Cx_CR.si is set to 1 if successful. Next, write the slave address and write bit (SLA+W) into I2Cx_DATA, and after clearing the "si" bit, SLA+W is sent on the bus.

Next, write the slave address and write bit (SLA+W) into I2Cx_DATA, and after clearing the "si" bit, SLA+W is sent on the bus. The data is then sent according to the user-defined format. After all the data is sent, set I2Cx_CR.sto to 1, clear the "si" bit and send a STOP signal, or send a repeated start signal for a new round of data transmission.

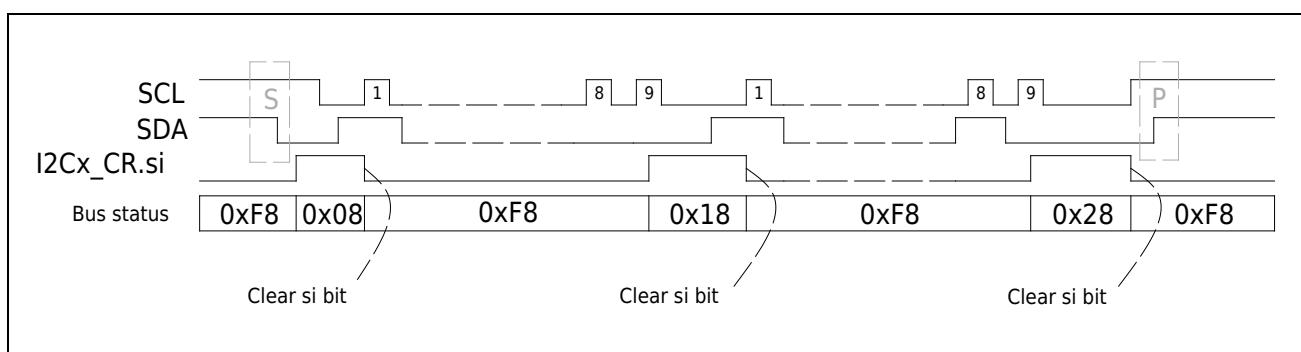

Figure 7-7 Data synchronization diagram of master sending mode

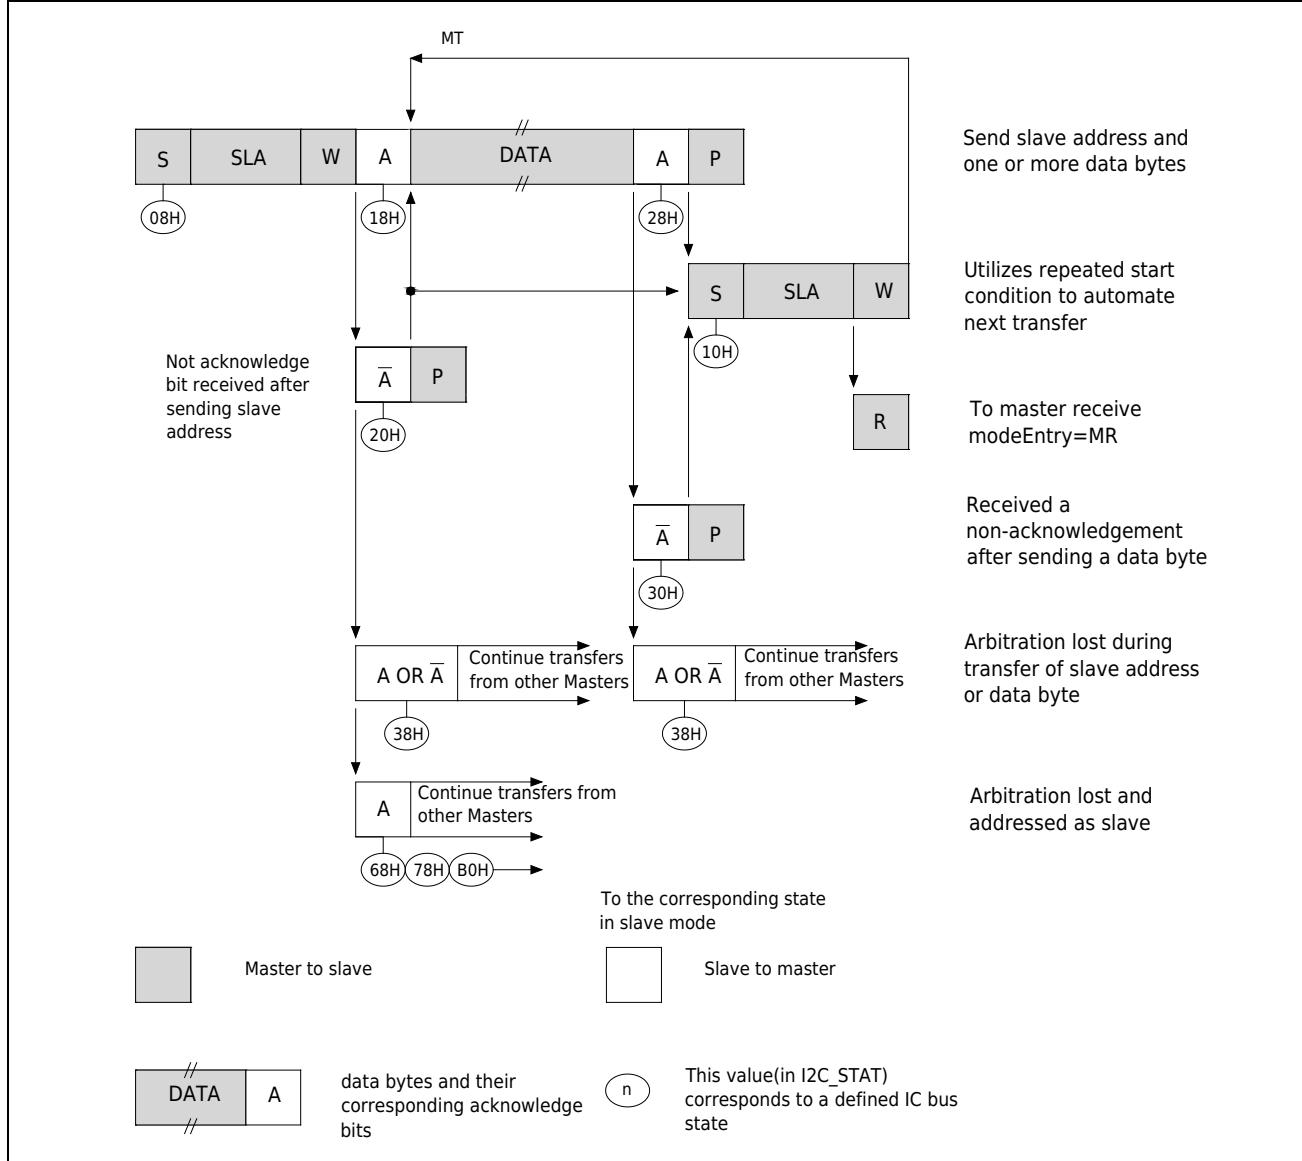

Figure 7-8 I2C master sending state diagram

■ Host receiving mode

The master receives the mode, and the data is transmitted by the slave. The initialization setting is the same as the master sending mode, after the master sends the start bit, I2Cx_DATA should be written to the slave address and "read bit" (SLA+R). I2Cx_CR.si is set to 1 after the slave acknowledge bit ACK is received. " si" is cleared to 0, it starts to receive slave data. If I2Cx_CR.aa is 1, the master responds with an acknowledgment bit after receiving the data; if it is 0, the master does not respond with a NACK after receiving the data. Then the Master can send a stop signal or repeat the start signal to start the next round of data transmission.

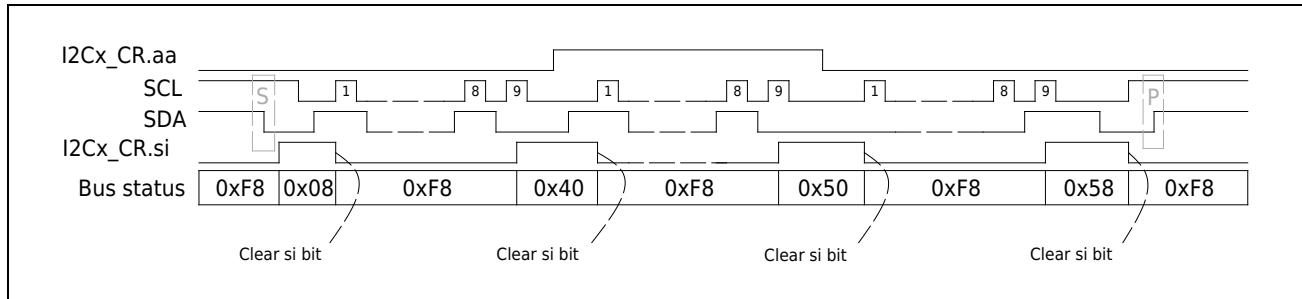

Figure 7-9 Data synchronization diagram of main receiving mode

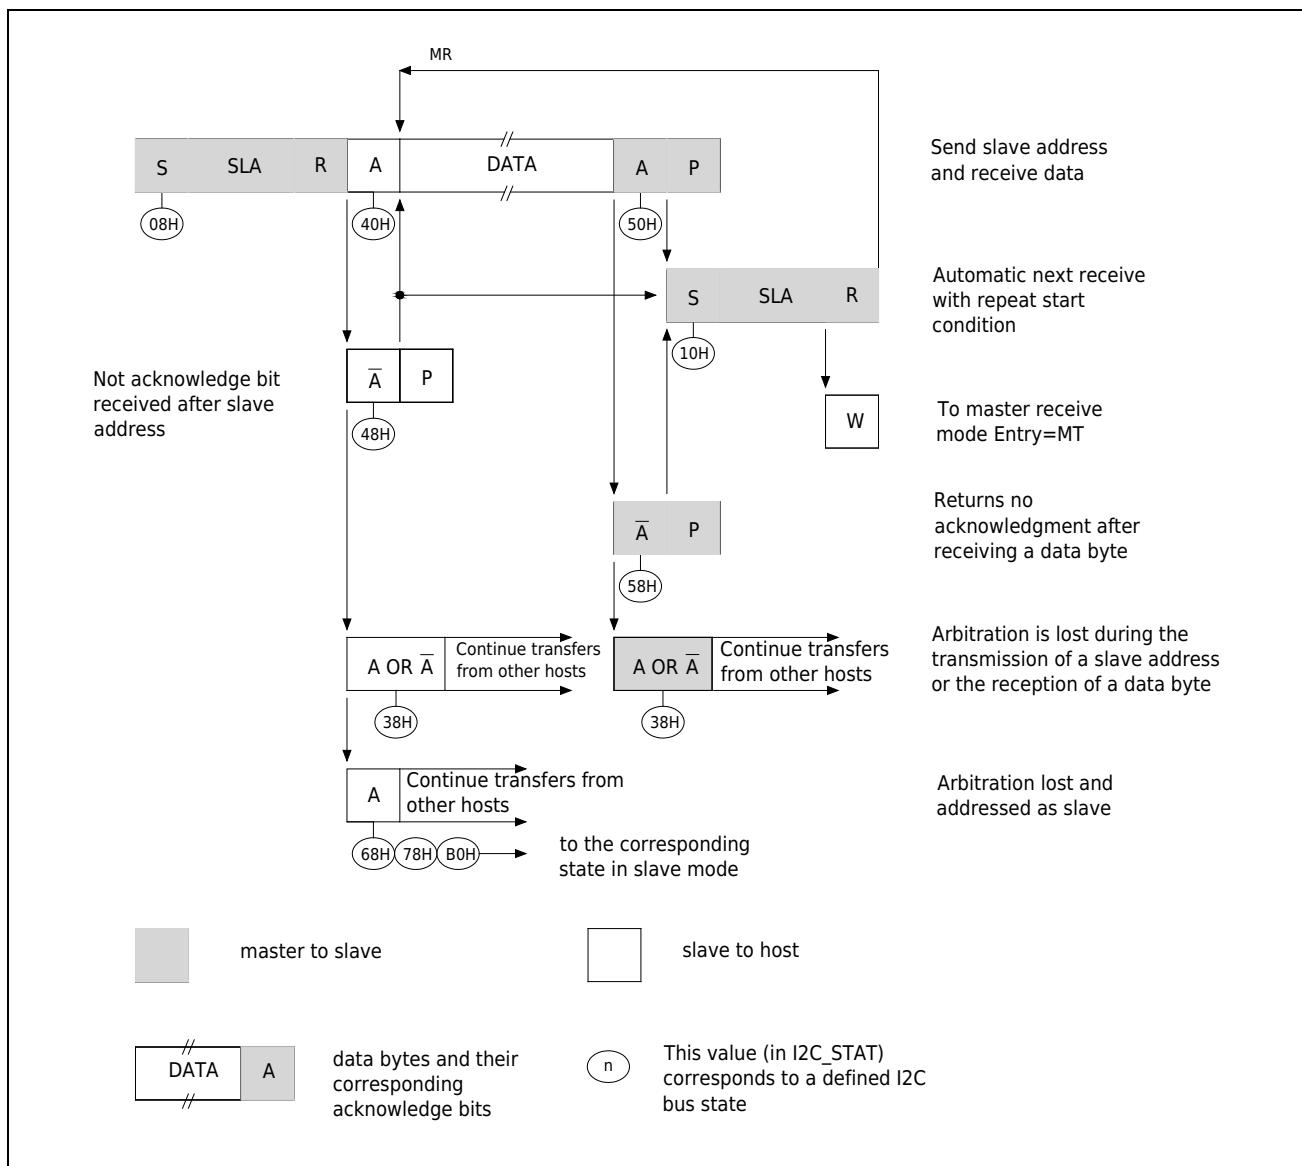

Figure 7-10 I2C master receiving state diagram

■ Slave receiving mode

In slave receiving mode, the slave receives data from the master. Before the transmission starts, I2Cx_ADDR should be written to the slave address, and I2Cx_CR.aa is set to 1 to respond to the addressing of the master. After the above initialization, the slave enters idle mode and waits for a "write" signal (SLA+W). If the master fails to arbitrate, it will also directly enter the slave

receiving mode.

When the slave is addressed by the "write" signal SLA+W, the "si" bit needs to be cleared to receive data from the master. I2Cx_CR.aa=0 during the transmission, the slave will return NACK in the next byte, the slave will also turn into an unaddressed slave, the connection with the master is terminated, no more data is received, and I2C_DATA remains before received data.

Slave address recognition can be restored by setting "aa", which means that the "aa" bit temporarily detaches the I2C module from the I2C bus.

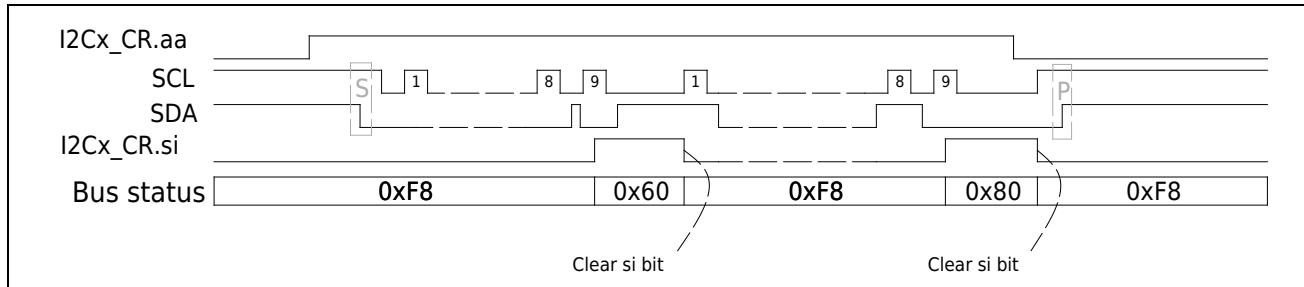

Figure 7-11 Slave Receive Mode Data Synchronization Diagram

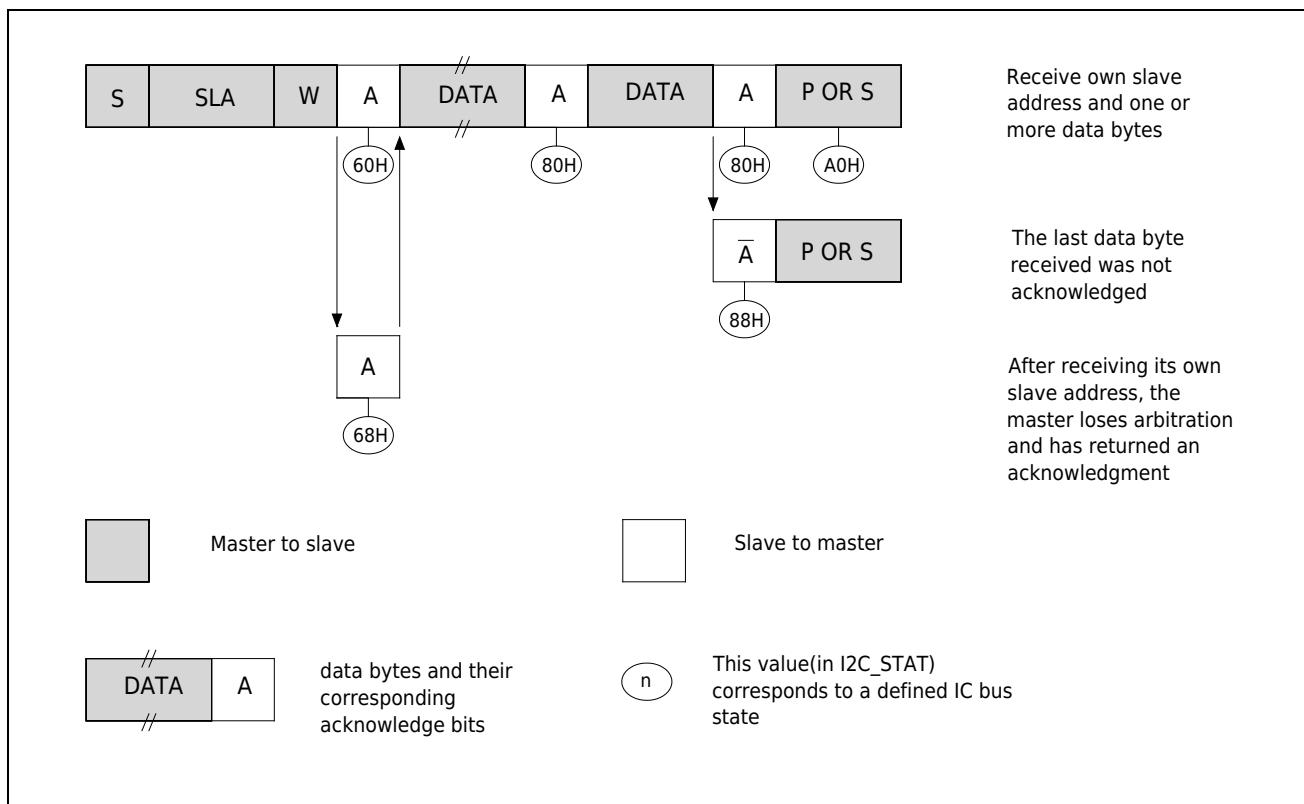

Figure 7-12 Slave receiving state diagram

■ Slave mode

In the slave sending mode, the data is sent from the slave to the master. After initializing the I2Cx_ADDR and I2Cx_CR.aa values, the device waits until its own address is addressed by the "read" signal (SLA+R). If the master fails to arbitrate, it can also enter the slave sending mode. When the slave is addressed by the "read" signal SLA+R, "si" needs to be cleared to send data to the master. Normally the Master returns an acknowledge bit after each byte of data received. I2Cx_CR.aa is cleared during transmission, the slave will send the last byte of data, and send all 1 data in the next transmission, and turn itself into an unaddressed slave.

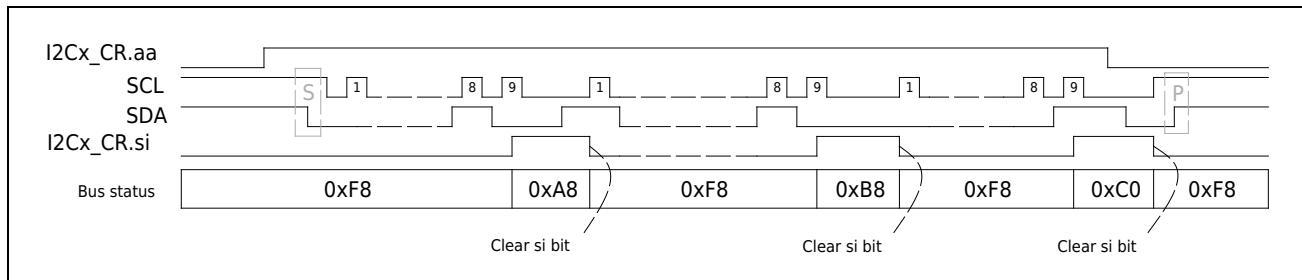

Figure 7-13 Slave mode data synchronization diagram

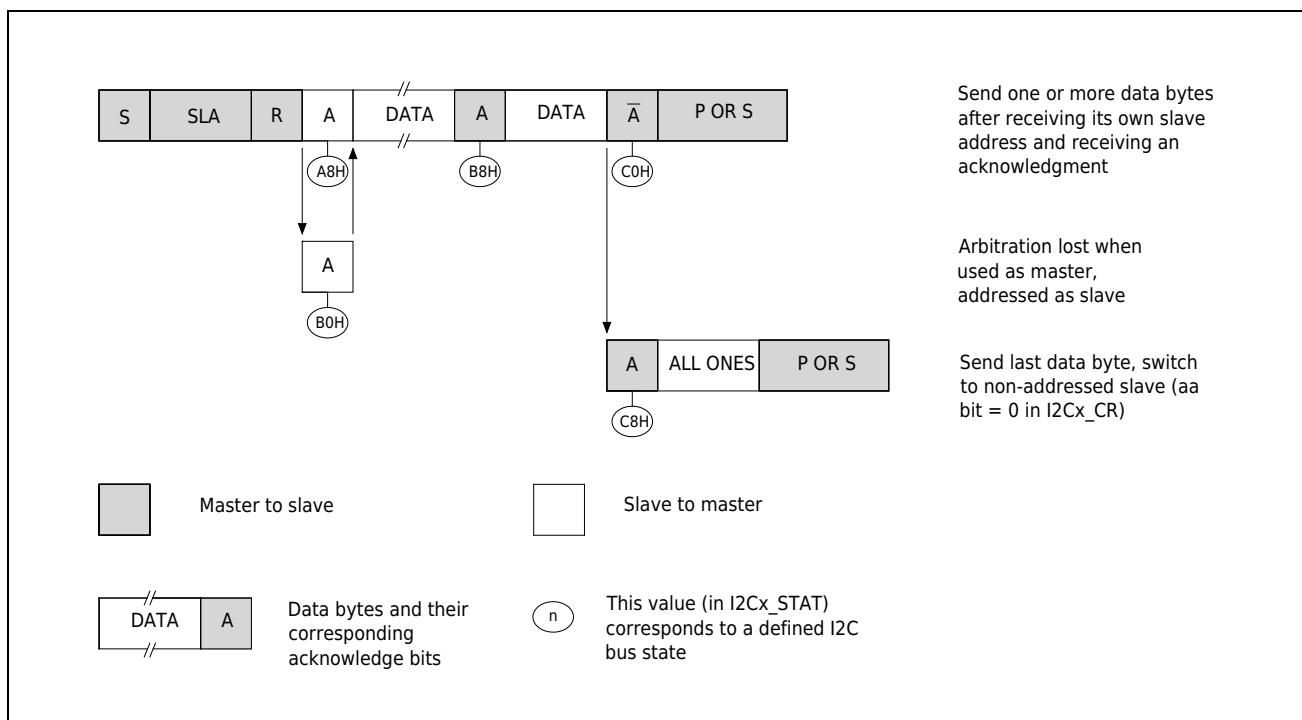

Figure 7-14 I2C Slave Transmit State Diagram

■ General call mode

General call mode is a special slave receiving mode. The addressing mode is 0x00, and the slave address and reading and writing are both 0. When both I2Cx_ADDR.GC and I2Cx_CR.aa are set to 1, the general call mode is enabled. In this mode, the I2Cx_STAT value is different from the normal slave receiver mode I2Cx_STAT value. Arbitration failure may also enter general call mode.

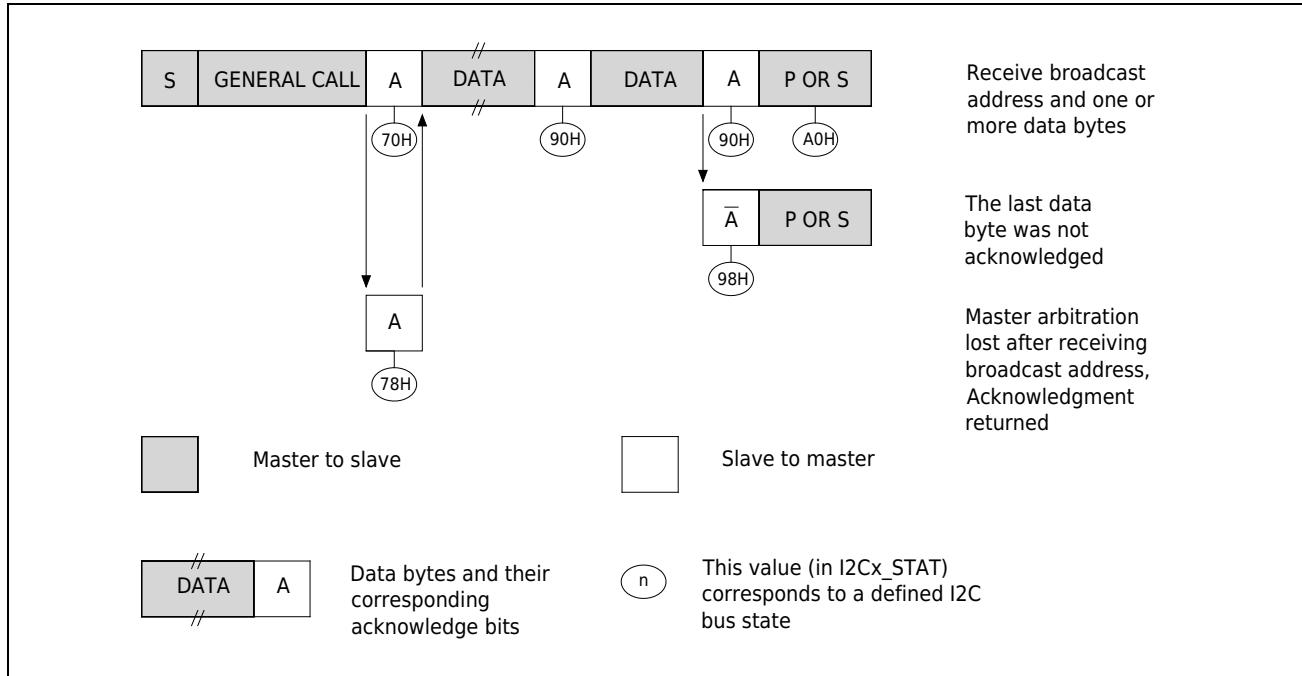

Figure 7-15 I2C General Call State Diagram

7.4.7 Status code expression

There are two special states in the I2C status register: F8H and 00H.

F8H: This status code indicates that no relevant information is available, because the serial interrupt flag "si" has not been set. This condition occurs between other states and before the I2C module has started to perform a serial transfer.

00H: This status code indicates that a bus error occurred during I2C serial transmission. A bus error occurs when a START or STOP condition occurs at an illegal position in a format frame. These illegal locations refer to address bytes, data bytes, or acknowledge bits during serial transfers. When external disturbances affect the internal I2C block signals, "si" is set when a bus error occurs.

Table 7-2 I2C status code expression

Status code	Description
Master sending mode	
08H	Start condition sent
10H	Repeated start condition sent
18H	SLA+W sent, ACK received
20H	SLA+W sent, not ACK received
28H	Data in I2Cx_DATA has been sent, ACK has been received
30H	Data in I2Cx_DATA sent, not ACK received
38H	Loss of Arbitration when SLA+ reads or writes data bytes
Main receiving mode	
08H	Start condition sent
10H	Repeated start condition sent
38H	Arbitration lost in non- ACK
40H	SLA+R sent, ACK received
48H	SLA+R sent, not ACK received
50H	Data byte has been received, ACK has been returned
58H	Data bytes received, non- ACK returned
Slave receive mode	
60H	Has received its own SLA+W and returned ACK
68H	When the master is in SLA+ read and write lost arbitration, has received its own SLA+W, and has returned ACK
80H	The previous addressing used its own slave address, received data bytes, and returned ACK
88H	The previous addressing used its own slave address, received data bytes, and returned non- ACK
A0H	When statically addressed, a STOP condition or a repeated START condition is received
Slave send mode	
A8H	Received its own SLA+R and returned ACK
B0H	When the Master loses arbitration, has received its own SLA+R, and has returned ACK
B8H	ACK received
C0H	Data bytes sent, not ACK received
C8H	Loaded data bytes have been sent, ACK has been received
general call mode	
70H	Received broadcast address (0x00), returned ACK
78H	When the master is in SLA+ read and write lost arbitration, the broadcast address has been received, and ACK has been returned
90H	The previous addressing used the broadcast address, data bytes have been received, and ACK has been returned

Status code	Description
98H	The previous addressing used the broadcast address, the data byte has been received, and a non- ACK has been returned
A0H	When statically addressed, a STOP condition or a repeated START condition is received
Other miscellaneous status	
F8H	No relevant status information available, si=0
00H	A bus error occurs during transmission, or external interference causes I2C to enter an undefined state

7.5 Programming example

7.5.1 Master sending example

Step1: Set PERI_CLKEN0.I2Cx to 1 to enable the I2Cx module clock.

Step2: Write 0 and 1 to PERI_RESET.I2Cx in sequence to reset the I2Cx module.

Step3: Configure the ports used by SCL and SDA of I2C as open-drain mode, and configure the appropriate port direction according to the I2C mode (for example, if the port direction is configured as output, the corresponding output register needs to be initialized before the corresponding bit of DIR is cleared. 1) and finally map SCL and SDA to corresponding pins.

Step4: Configure I2Cx_TM to make the clock rate of SCL meet the application requirements.

Step5: Set I2Cx_TMRUN to 1, enable SCL clock generator.

Step6: Set I2Cx_CR.ens to 1 to enable the I2C module.

Step7: Set I2Cx_CR.sta to 1, the bus tries to send the Start signal.

Step8: Wait for I2Cx_CR.si to become 1, the Start signal has been sent to the bus.

Step9: Query I2Cx_STAT, if the value of this register is 0x08 or 0x10, proceed to the next step, otherwise perform error handling.

Step10: Write SLA+W to I2Cx_DATA, set I2Cx_CR.sta to 0, set I2Cx_CR.si to 0, and send SLA+W.

Step11: Wait for I2Cx_CR.si to become 1, SLA+W has been sent to the bus.

Step12: Query I2Cx_STAT, if the register value is 0x18, proceed to the next step. Otherwise, perform error handling.

Step13: Write the data to be sent to I2Cx_DATA, set I2Cx_CR.si to 0, and send the data.

Step14: Wait for I2Cx_CR.si to become 1, the data has been sent to the bus.

Step15: Query I2Cx_STAT, if the register value is 0x28, proceed to the next step. Otherwise, perform error handling.

Step16: If the data to be sent is not completed, then jump to Step13 to continue execution.

Step17: Set I2Cx_CR.sto to 1, set I2Cx_CR.si to 0, and the bus tries to send a Stop signal.

7.5.2 Master receive example

Step1: Set PERI_CLKEN0.I2Cx to 1 to enable the I2Cx module clock.

Step2: Write 0 and 1 to PERI_RESET.I2Cx in sequence to reset the I2Cx module.

Step3: Configure the ports used by SCL and SDA of I2C as open-drain mode, and configure the appropriate port direction according to the I2C mode (for example, if the port direction is configured as output, the corresponding output register needs to be initialized before the corresponding bit of DIR is cleared. 1) and finally map SCL and SDA to corresponding pins.

Step4: Configure I2Cx_TM to make the clock rate of SCL meet the application requirements.

Step5: Set I2Cx_TMRUN to 1, enable SCL clock generator.

Step6: Set I2Cx_CR.ens to 1 to enable the I2C module.

Step7: Set I2Cx_CR.sta to 1, the bus tries to send the Start signal.

Step8: Wait for I2Cx_CR.si to become 1, the Start signal has been sent to the bus.

Step9: Query I2Cx_STAT, if the register value is 0x08 or 0x10, continue to the next step, otherwise, perform error handling.

Step10: Write SLA+R to I2Cx_DATA, set I2Cx_CR.sta to 0, set I2Cx_CR.si to 0, and send SLA+R.

Step11: Wait for I2Cx_CR.si to become 1, SLA+R has been sent to the bus.

Step12: Query I2Cx_STAT, if the register value is 0x40, proceed to the next step, otherwise, perform error handling.

Step13: Set I2Cx_CR.aa to 1 to enable the response flag.

Step14: Set I2Cx_CR.si to 0, the slave sends data, and the master sends ACK or NACK according to I2Cx_CR.aa.

Step15: Wait for I2Cx_CR.si to become 1, read the received data from I2Cx_DATA.

Step16: Query I2Cx_STAT, if the value of this register is 0x50 or 0x58, continue to the next step, otherwise perform error handling.

Step17: If the data to be received is only the last byte, set I2Cx_CR.aa to 0 and enable the non-response flag.

Step18: If the data to be received is not completed, then jump to Step14 to continue execution.

Step19: Set I2Cx_CR.sto to 1, set I2Cx_CR.si to 0, and the bus tries to send a Stop signal.

7.5.3 Slave receiving example

Step1: Set PERI_CLKEN0.I2Cx to 1 to enable the I2Cx module clock.

Step2: Write 0 and 1 to PERI_RESET.I2Cx in sequence to reset the I2Cx module.

Step3: Configure the ports used by SCL and SDA of I2C as open-drain mode, and configure the appropriate port direction according to the I2C mode (for example, if the port direction is configured as output, the corresponding output register needs to be initialized before the corresponding bit of DIR is cleared. 1) and finally map SCL and SDA to corresponding pins.

Step4: Set I2Cx_CR.ens to 1 to enable the I2C module.

Step5: Configure I2Cx_ADDR as the slave address.

Step6: Set I2Cx_CR.aa to 1 to enable the response flag.

Step7: Wait for I2Cx_CR.si to become 1 and be addressed by SLA+W.

Step8: Query I2C x_STAT, if the value of this register is 0x60, proceed to the next step, otherwise perform error handling.

Step9: Set I2Cx_CR.si to 0, the Master sends data, and the slave returns ACK or NACK according to I2Cx_CR.aa.

Step10: Wait for I2Cx_CR.si to become 1, read the received data from I2Cx_DATA.

Step11: Query I2Cx_STAT, if the value of this register is 0x80, continue to the next step, otherwise perform error handling.

Step12: If the data to be received is not completed, then jump to Step9 to continue execution.

Step13: Set I2Cx_CR.aa to 0, and set I2Cx_CR.si to 0.

7.5.4 Slave sending example

Step1: Set PERI_CLKEN0.I2Cx to 1 to enable the I2Cx module clock.

Step2: Write 0 and 1 to PERI_RESET.I2Cx in sequence to reset the I2Cx module.

Step3: Configure the ports used by SCL and SDA of I2C as open-drain mode, and configure the appropriate port direction according to the I2C mode (for example, if the port direction is configured as output, the corresponding output register needs to be initialized before the corresponding bit of DIR is cleared. 1) and finally map SCL and SDA to corresponding pins.

Step4: Set I2Cx_CR.ens to 1 to enable the I2C module.

Step5: Configure I2Cx_ADDR as the slave address.

Step6: Set I2Cx_CR.aa to 1 to enable the response flag.

Step7: Wait for I2Cx_CR.si to become 1 and be addressed by SLA+R.

Step8: Query I2Cx_STAT, if the value of this register is 0xA8, proceed to the next step, otherwise, perform error handling.

Step9: Write the data to be sent to I2Cx_DATA, set I2Cx_CR.si to 0, and send the data.

Step10: Wait for I2Cx_CR.si to become 1, the data has been sent to the bus.

Step11: Query I2Cx_STAT, if the value of this register is 0xB8 or 0xC0, proceed to the next step, otherwise, perform error handling.

Step12: If the data to be sent is not completed, then jump to Step9 to continue execution.

Step13: Set I2Cx_CR.aa to 0, and set I2Cx_CR.si to 0.

8 Serial Peripheral Interface (SPI)

8.1 Introduction to SPI

The SPI interface is a synchronous serial data communication interface working in full-duplex mode, using 4 pins for communication: MISO, MOSI, SCK, CS/SSN. When SPI is used as the master, output CS and SCK signals to control the communication process. When SPI acts as a slave, it communicates under the control of SSN and SCK signals.

8.2 Main Features of SPI

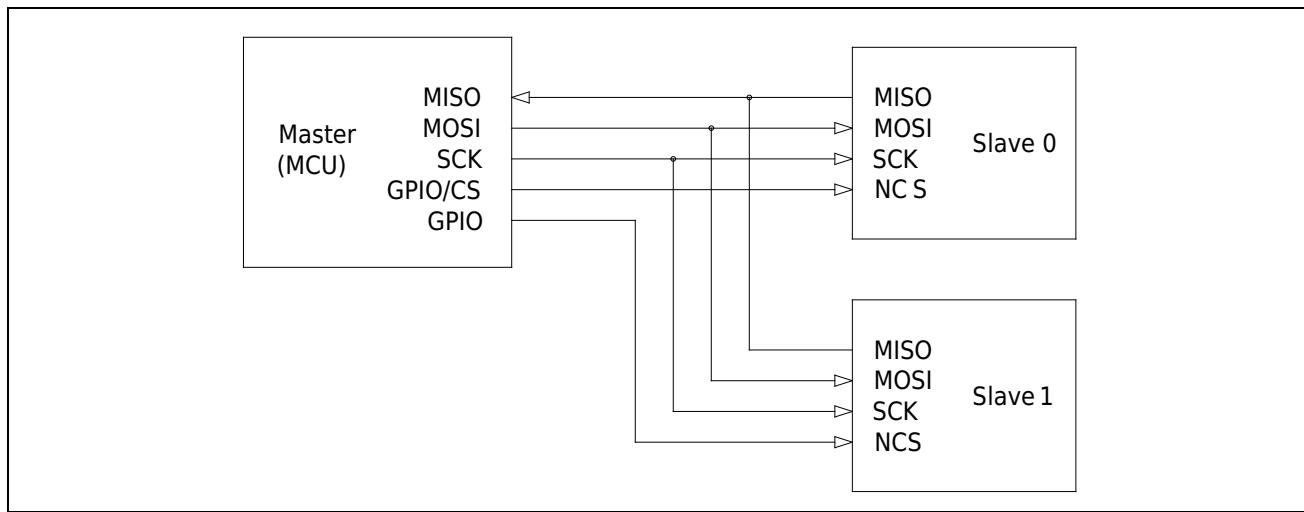

- Support SPI master mode, SPI slave mode
- Support standard four-wire full-duplex communication
- Supports configuration of serial clock polarity and phase
- Master mode supports 7 communication speeds
- The maximum frequency division factor of the host mode is PCLK/2
- The maximum frequency division factor of slave mode is PCLK/4
- The frame length is fixed at 8 bits, and the MSB is transmitted first
- Support DMA software/hardware access

8.3 SPI Functional Description

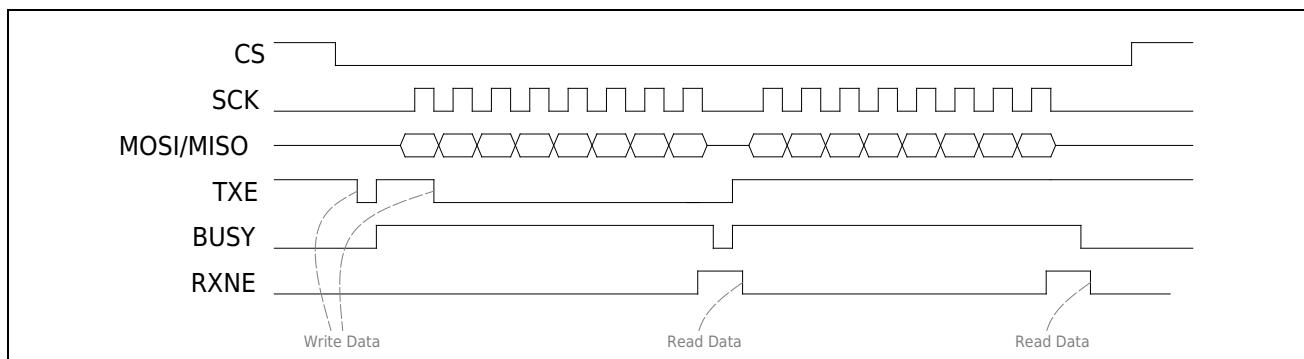

8.3.1 SPI master mode

The length of each data frame is fixed at 8 bits, and the first bit of sent data is fixed at MSB. Set SPIx_CR.mstr to 1, the SPI interface works in master mode. Write data into the SPIx_Data register to start SPI transmission, and the SCK pin will automatically generate a serial clock; on the edge of the serial clock, the data in the shift register is sent to the MOSI pin, and the data on the MISO pin is received into the shift register. SCK pin output clock is controlled by SPIx_CR[spr2:spr0], and the output frequency range is PCLK /2~PCLK/128; the output level of the CS pin is controlled by SPIx_SSN.ssn, and the output of the GPIO pin The level is controlled by GPIO related registers.

A typical application block diagram of master mode is shown below.

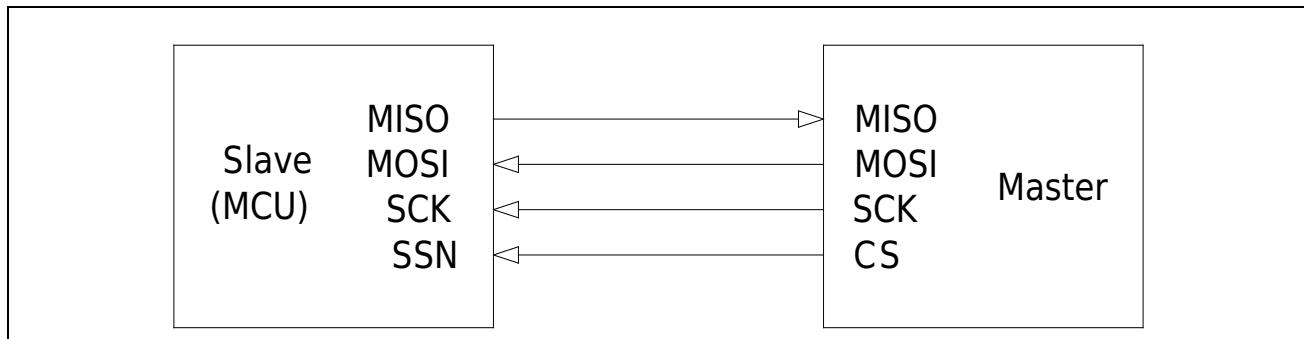

The communication diagram of the master mode is shown in the figure below, where CPOL=0, CPHA=0.

8.3.2 SPI slave mode

The length of each data frame is fixed at 8 bits, and the first bit of received data is fixed at MSB. Set SPIx_CR.mstr to 0, the SPI interface works in slave mode. In this mode, the SCK pin is used as an input pin and the serial clock comes from an external Master; the SSN pin is used as an input pin and the chip select signal comes from an external Master or is fixed at low level. GPIO chapter for details on the SSN pins. A typical application block diagram of the slave mode is shown below.

When the SPI slave receives a byte of data from the SPI master, the RXNE bit will be set high; the user program should read the received data as soon as possible. The communication timing of receiving data in slave mode is as follows, where CPOL=0, CPHA=0.

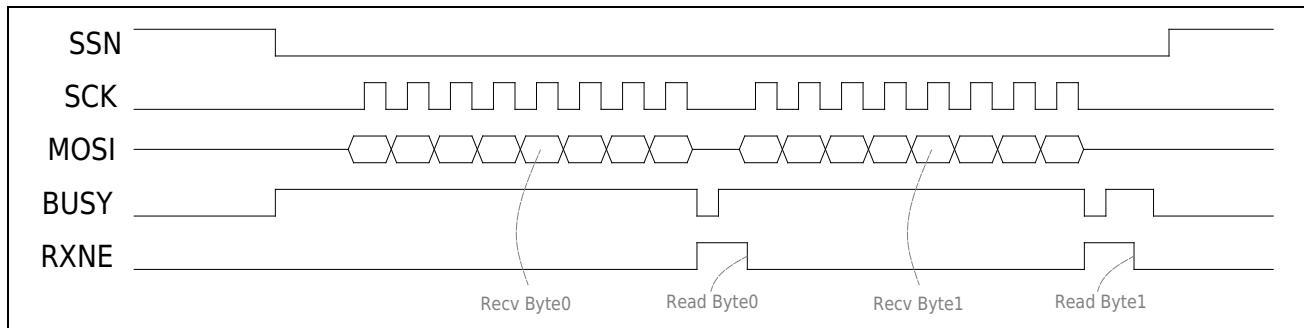

Figure 8-1 Slave receiving diagram

When the SPI slave needs to send data to the Master, the following five steps should be performed in sequence before the Master pulls down NSS: set the PERI_RESET0.SPIx bit to 0, set the PERI_RESET0.SPIx bit to 1, configure the SPI communication parameters, and write to the SPIx_DATA register. Write the first byte of data to be sent; after NSS is pulled low, whenever the TXE flag is 1, the subsequent data to be sent should be written to the SPIx_DATA register as soon as possible. The communication timing of sending data in slave mode is as follows, where CPOL=0, CPHA=0.

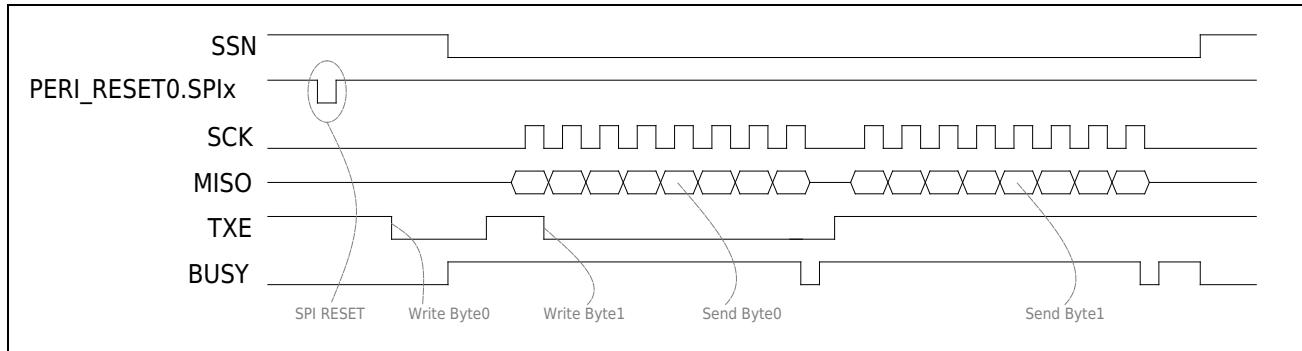

Figure 8-2 Slave sending diagram

8.3.3 SPI data frame format

The SPI interface frame format depends on the configuration of clock polarity bit CPOL and clock phase bit CPHA.

When CPOL is 0, the idle state of SCK line is low. When CPOL is 1, the idle state of SCK line is high level. When CPHA is 0, the data will be sampled when the first SCK clock transition signal jumps. When CPHA is 1, the data will be sampled when the second SCK clock signal jumps.

The frame format of the SPI interface master is shown in the figure below.

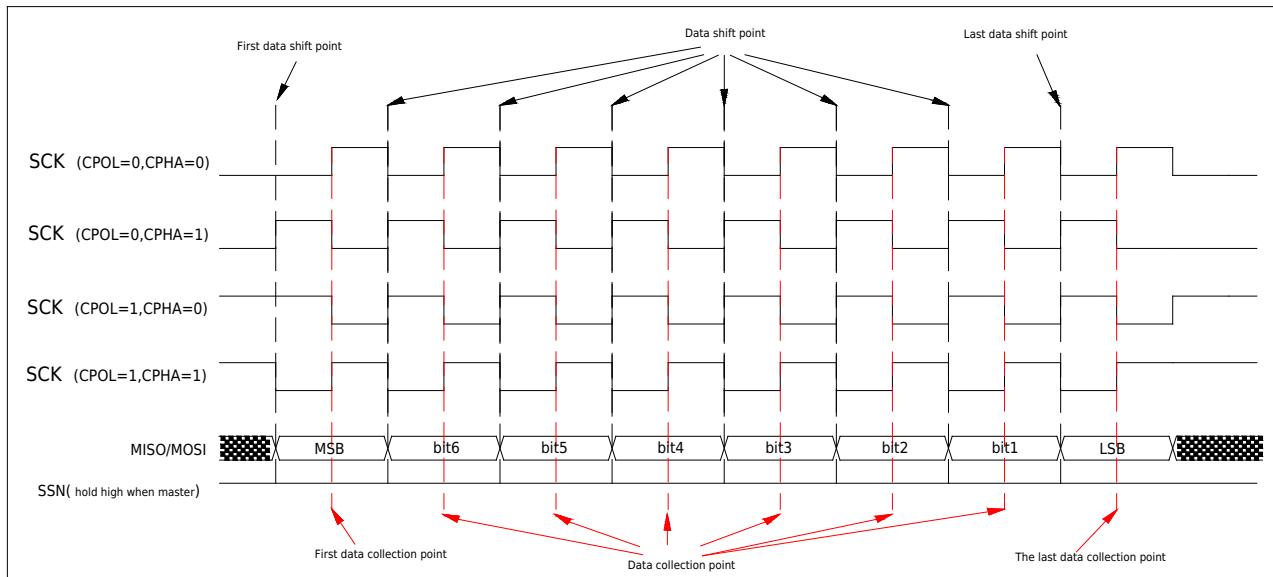

Figure 8-3 Host Mode Frame Format

The SPI interface slave frame format is shown in the figure below.

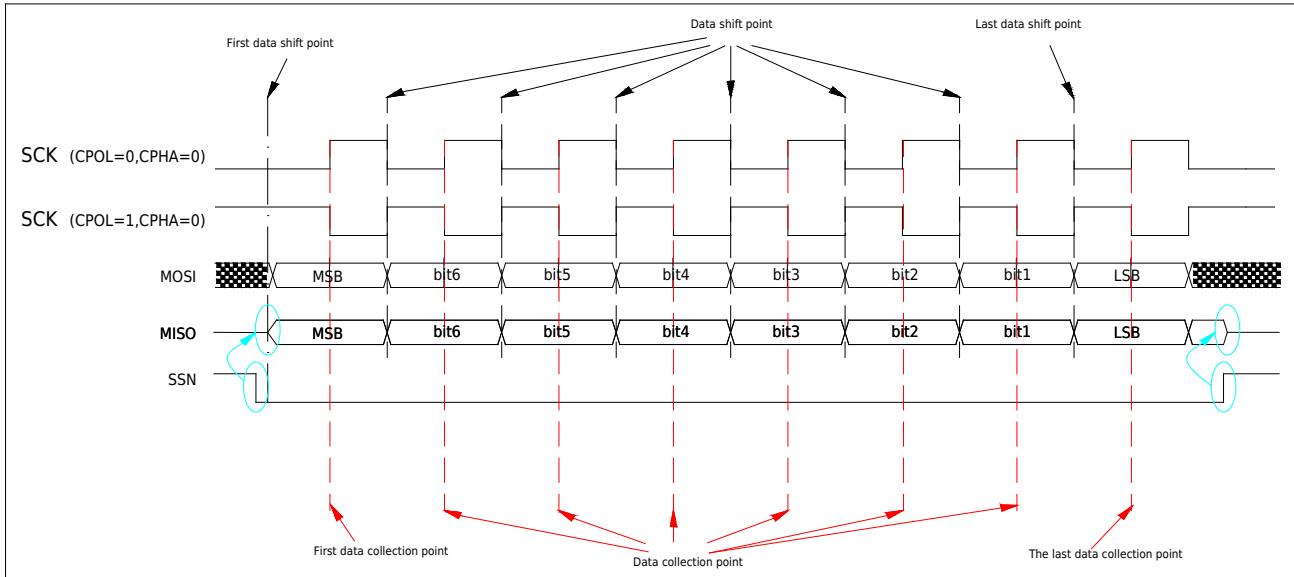

Figure 8-4 Data frame format when slave CPHA is 0

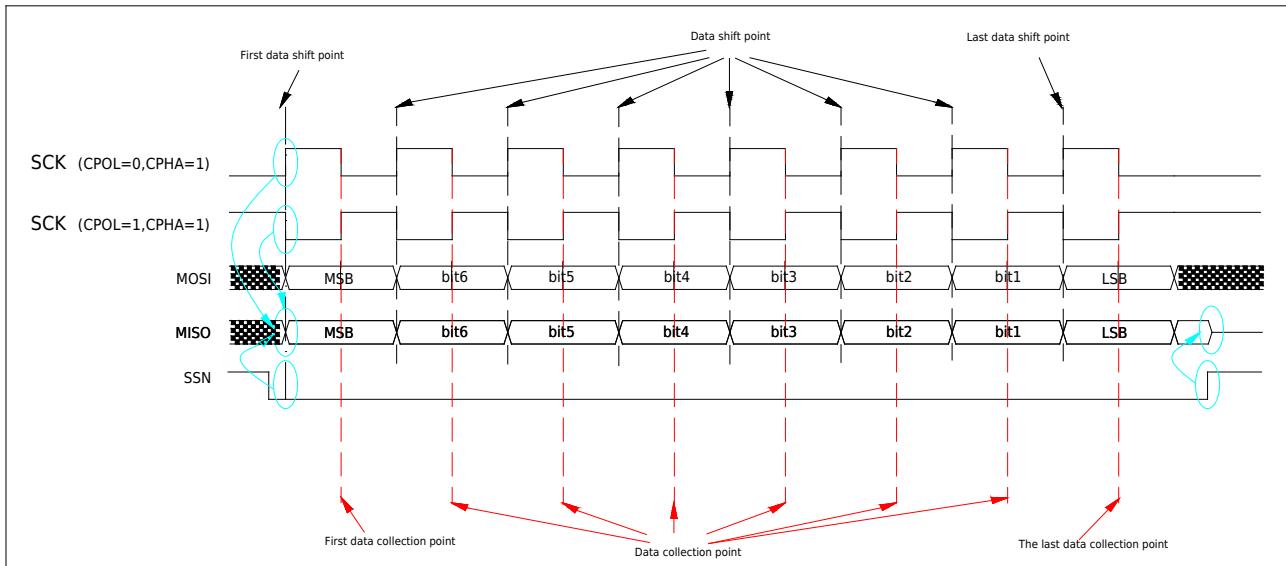

Figure 8-5 Data frame format when slave CPHA is 1

8.3.4 SPI Status Flags and Interrupts

SPI will generate the following four status flags during work, and the generation conditions and clearing methods are as follows.

- When the data in the send buffer (SPIx_Data) is transferred to the send shift register, SPIx_STAT.txe will be set by hardware, indicating that the send buffer is empty and the next data can be written. To SPIx_DATA clears this flag.
- When the data in the receiving shift register is transferred to the receiving buffer (SPIx_Data), SPIx_STAT.rxne will be set by hardware, indicating that the receiving buffer is not empty, and the user needs to read the data as soon as possible. This flag can be cleared by reading data from SPIx_DATA.
- When the SPI works in master mode and the external SSN input is low, SPIx_STAT.mdf will be set by hardware, indicating that other SPI masters are occupying the bus. When the SSN input is high, SPIx_STAT.mdf will be automatically cleared by hardware.
- When the SPI works in slave mode, if the SSN pin is pulled high during data transmission, SPIx_STAT.sserr will be set. Set SPIx_CR.spen to 0 to clear this flag.

If the SPI interrupt is enabled (SPIx_CR2.int_en=1), the following three situations can generate an interrupt:

- The SPI transmit buffer is empty, that is, SPIx_STAT.txe is 1
- SPI receive buffer is not empty, that is, SPIx_STAT.rxne is 1
- SPI is wrong, that is, SPIx_STAT.mdf is 1

In the interrupt service routine, it is necessary to write 0x00 to SPIx_ICLR to clear the internal interrupt flag.

8.3.5 SPI multi-machine system configuration instructions

- When the SPI module works as a master and works in a single-master system, the slave can be controlled through the SPI_CS pin or GPIO pin. SPI_CS pin is selected as the chip select signal of the slave, set SPIx_SSNS.ssn to 0 to select the slave, and set SPIx_SSNS.ssn to 1 to release the slave. GPIO pin is selected as the chip select signal of the slave, set the corresponding bit of the GPIOx_OUT register to 0 to select the slave, and set the corresponding bit of the GPIOx_OUT register to 1 to release the slave.
- When the SPI module is a slave, configure the source of SPI_SSNS as needed (see GPIO port auxiliary controller for details). When the SSN is low, the slave machine can be selected for communication; when the SSN is high, the machine is in an unselected state.
- When the SPI mode works on multi-master and multi-slave, all slave chip select signals are connected through GPIO pins, and the master must also be connected to the SSN signals of other masters through GPIO pins to monitor whether the bus is occupied. Master0 needs to communicate as shown in the figure below is: wait for Master0.SSN to become high; output low

from GPIO0 to notify Master1 to release the SPI bus; output low from GPIO2 to select Slave1; communicate with Slave1; output high from GPIO2 to release Slave1; output high from GPIO0 to release Master1.

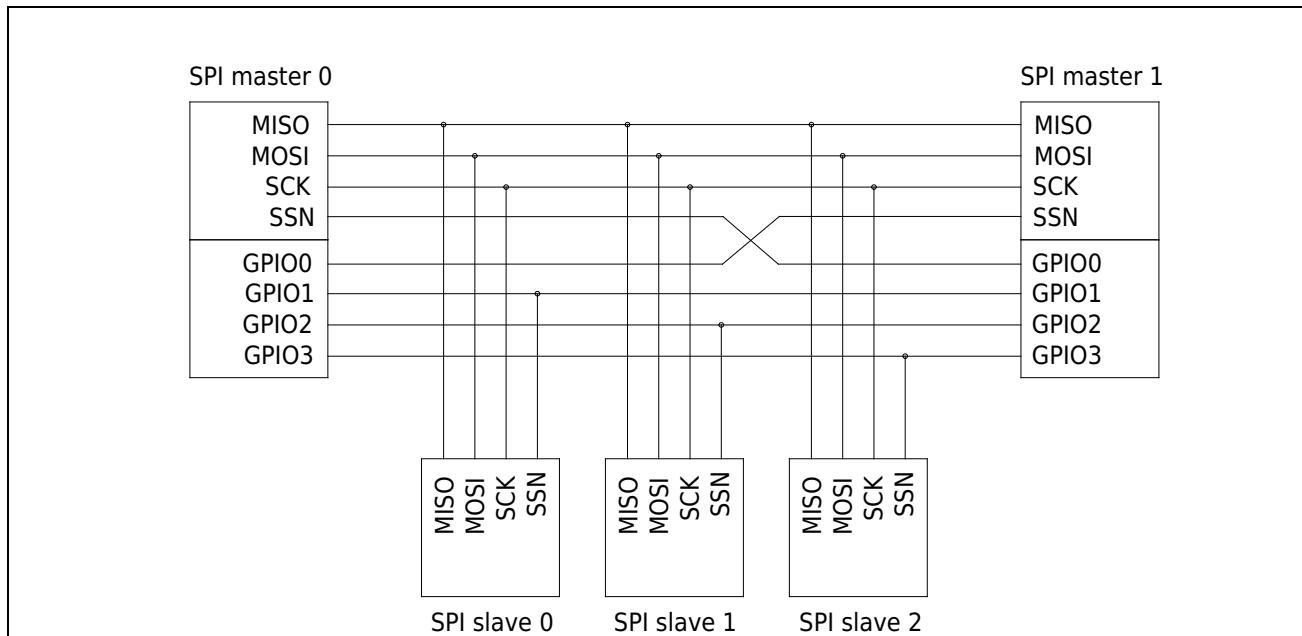

Figure 8-6 Schematic diagram of SPI multi-master/multi-slave system

8.3.6 SPI pin configuration description

SPI can maintain some or all functions under some special pin configurations.

The specific situation is as follows ("✓" means that the pin is configured and used, and blank means that the pin is not configured):

Table 8-1 SPI pin configuration description table

	SPI_CS(Master) / SPI_SSN (slave)	SCK	MOSI	MISO	Functional description
Host mode	✓	✓	✓	✓	general configuration All Masters function normally
		✓	✓	✓	All Masters function normally
	✓	✓	✓		Master sending function is normal
	✓	✓		✓	Master receiving function is normal
		✓	✓		Master sending function is normal
		✓		✓	Master receiving function is normal
Slave mode	✓	✓	✓	✓	general configuration All slaves function normally
	✓	✓	✓		Slave receiving function is normal
	✓	✓		✓	Slave sending function is normal
	✓ fixed low level	✓	✓	✓	All slaves function normally
	✓ fixed low level	✓	✓		Slave receiving function is normal
	✓ fixed low level	✓		✓	Slave sending function is normal

Note:

- Conditions not listed in the table are currently not supported.
- In master mode, even if the SPIx_CS chip select output is not used, SPIx.SSN needs to be set to 1 before sending data, and SPIx.SSN needs to be set to 0 after sending data.
- In slave mode and chip select input is fixed at low level, in order to maintain normal function, SPIx_CR.cpha=1 must be satisfied.

8.4 SPI programming example

8.4.1 SPI master sending example

Step1: Map CS/SCK/MISO/MOSI to the required pins according to the relevant description of the pin digital multiplexing function in the GPIO chapter; configure the CS/SCK/MOSI pins as output mode, and configure the MISO pin as input mode.

Step2: Set SPIx_CR.mstr to 1 to make SPI work in master mode.

Step3: Configure SPIx_CR[spr2:spr0] to make the clock rate of SCK output meet the application requirements.

Step4: Configure SPIx_CR.cpol and SPIx_CR.cpha to make the data frame format meet the application requirements.

Step5: Set SPIx_CR.spen to 1 to enable the SPI interface.

Step6: Set SPIx_SSN.ssn to 0, make the CS pin output low level to select the slave.

Step7: When SPIx_STAT.txe is 1, write the data to be sent to SPIx_DATA as soon as possible.

Step8: If the data to be sent is not completed, then jump to Step7 to continue execution.

Step9: The query waits for SPIx_STAT.txe to become 1, and the last byte data has been sent.

Step10: Query and wait for SPIx_STAT.busy to become 0, the SPI bus is idle.

Step11: Set SPIx_SSN.ssn to 1, make the CS pin output high level to release the slave.

Note:

- GPIO can be used instead of CS to realize chip select output, which is mostly used in multi-machine communication system.
- SPIx_SSN.ssn must be set to 0 during the transmission process, and SPIx_SSN.ssn must be set to 1 after the transmission is completed.

8.4.2 SPI master receive example

Step1: Map CS/SCK/MISO/MOSI to the required pins according to the relevant description of the pin digital multiplexing function in the GPIO chapter; configure the CS/SCK/MOSI pins as output mode, and configure the MISO pin as input mode.

Step2: Set SPIx_CR.mstr to 1 to make SPI work in master mode.

Step3: Configure SPIx_CR[spr2:spr0] to make the clock rate of SCK output meet the application requirements.

Step4: Configure SPIx_CR.cpol and SPIx_CR.cpha to make the data frame format meet the application requirements.

Step5: Set SPIx_CR.spen to 1 to enable the SPI interface.

Step6: Set SPIx_SSN.ssn to 0, make the CS pin output low level to select the slave.

Step7: Write arbitrary data to SPIx_DATA to trigger the Master to send SCK.

Step8: Query and wait for SPIx_STAT.rxne to become 1, and the data sent by the slave has been received.

Step9: Read the received data from SPIx_DATA.

Step10: If the data to be received is not completed, then jump to Step7 to continue execution.

Step11: Set SPIx_SSN.ssn to 1, make the CS pin output high level to release the slave.

Note:

- GPIO can be used instead of CS to realize chip select output, which is mostly used in multi-machine communication system.
- SPIx_SSN.ssn must be set to 0 during the transmission process, and SPIx_SSN.ssn must be set to 1 after the transmission is completed.

8.4.3 SPI slave sending example

Step1: Map SSN/SCK/MISO/MOSI to the required pins according to the relevant description of the pin digital multiplexing function in the GPIO chapter; and configure the SSN/SCK/MOSI pins as input mode, and configure the MISO pin as output mode. SSN pins, see GPIO Port Auxiliary Controller.

Step2: Set PERI_RESET0.SPIx to 0, so that the SPI module is in reset state.

Step3: Set PERI_RESET0.SPIx to 1 to make the SPI module work.

Step4: Set SPIx_CR.mstr to 0 to make SPI work in slave mode.

Step5: Configure SPIx_CR.cpol and SPIx_CR.cpha to make the data frame format meet the application requirements.

Step6: Set SPIx_CR.spen to 1 to enable the SPI interface.

Step7: Write the first byte data to be sent into SPIx_DATA.

Step8: The query waits for the SSN pin to be pulled low, and the master selects the SPI slave.

Step9: When SPIx_STAT.txe is 1, write the data to be sent to SPIx_DATA as soon as possible.

Step10: When it is found that the SSN pin is low and the data to be sent has not been completed, jump to Step9.

Step11: The query waits for the SSN pin to be pulled high, and the master releases the SPI slave.

Note:

- Whenever the SPI slave needs to send data, it needs to start the initialization operation and sending operation from Step2.

8.4.4 SPI Slave Receive Example

Step1: Map SSN/SCK/MISO/MOSI to the required pins according to the relevant description of the pin digital multiplexing function in the GPIO chapter; and configure the SSN/SCK/MOSI pins as input mode, and configure the MISO pin as output mode. SSN pins, see GPIO Port Auxiliary Controller.

Step2: Set SPIx_CR.mstr to 0 to make SPI work in slave mode.

Step3: Configure SPIx_CR.cpol and SPIx_CR.cpha to make the data frame format meet the application requirements.

Step4: Set SPIx_CR.spen to 1 to enable the SPI interface.

Step5: The query waits for the SSN pin to be pulled low, and the master selects the SPI slave.

Step6: Query and wait for SPIx_STAT.rxne to become 1, and the data sent by the Master has been received.

Step7: Read the received data from SPIx_DATA.

Step8: If the data to be received is not completed, then jump to Step6 to continue execution.

Step9: The query waits for the SSN pin to be pulled high, and the master releases the SPI slave.

9 Clock Trim Module (CLKTRIM)

9.1 Introduction to CLKTRIM

The CLKTRIM (Clock Trimming) module is a circuit specially used to calibrate / monitor the clock. In the calibration mode, select an accurate clock source to calibrate the inaccurate clock source, repeat the calibration, and adjust the parameters of the inaccurate clock source until the frequency of the calibrated clock source meets the accuracy requirements. In the calibration mode, the count value will have a certain error, but it is within the allowable precision error range. In the monitoring mode, select a stable clock source to monitor the system's working clock. Under the set monitoring period, monitor whether the system's working clock is invalid and generate an interrupt. In the calibration mode and monitoring mode, the required clock sources must be initialized and enabled. For the specific configuration process, please refer to the [System Controller (SYSCTRL)] chapter.

9.2 CLKTRIM main features

CLKTRIM supports the following features:

- Calibration mode
- Monitoring mode
- 32-bit reference clock counter can be loaded with initial value
- 32-bit clock counter to be calibrated with configurable overflow value
- 6 reference clock sources
- 6 clock sources to be calibrated
- Support interrupt mode

9.3 CLKTRIM function description

9.3.1 CLKTRIM calibration mode

9.3.1.1 Principle of Clock Calibration

When calibrating a clock whose frequency is inaccurate but has parameter settings to adjust the frequency (the clock to be calibrated CAL_CLK), an accurate clock is required as the reference clock (REF_CLK). Set the calibration time Ttrim, the frequency of the clock to be calibrated Fcal, and the frequency of the reference clock Fref, use the clock to be calibrated and the reference clock to count simultaneously, and stop counting at the end of the calibration time. M of the clock counter to be calibrated, the value N of the reference clock counter,

Get the equation $T_{trim} = M/F_{cal} = N/F_{ref}$

Deduce $F_{cal} = F_{ref} * M / N$

Judging from the formula, the smaller the frequency error rate of the reference clock is, the smaller the error rate of the clock to be calibrated is.

After calculating the frequency of the clock to be calibrated, if the error rate exceeds the range required by the system, you can adjust the parameters of the clock to be calibrated, and then repeat the above steps to calibrate until the error rate of the clock frequency to be calibrated meets the system requirements.

9.3.1.2 Clock Calibration Module Hardware Structure

There are 6 clock sources for the clock to be calibrated in the time calibration module, and 6 clock sources for the reference clock, as shown in Figure 9-1:

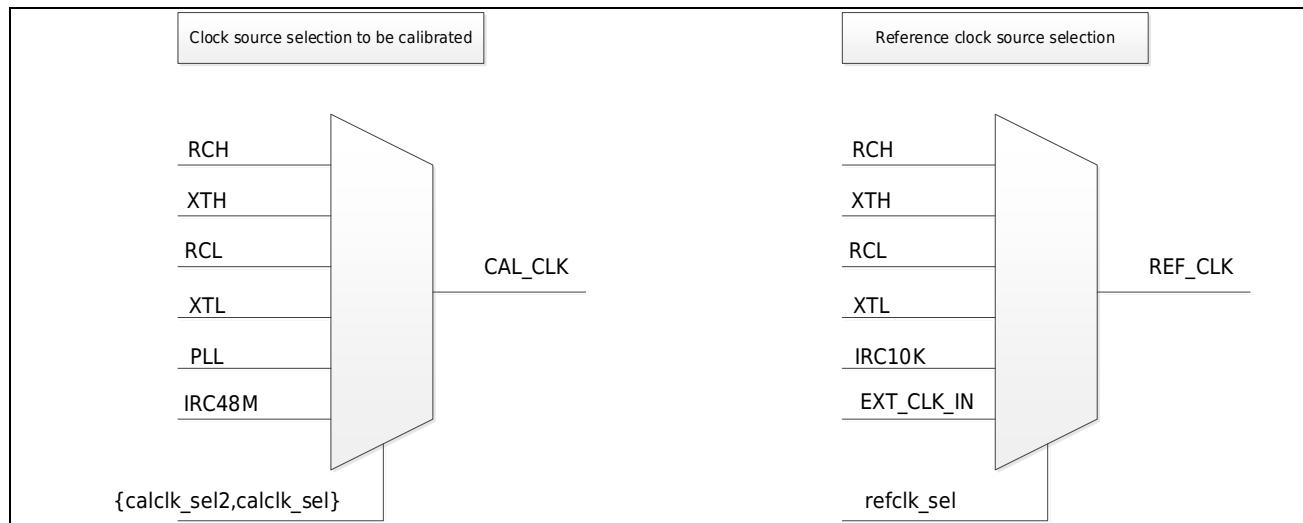

Figure 9-1 Schematic diagram of clock source selection

The selection of the clock to be calibrated is configured by registers CLKTRIM_CR.calclk_sel2 and CLKTRIM_CR.calclk_sel.

The selection of the reference clock is configured by the register CLKTRIM_CR.refclk_sel.

As shown in Figure 9-2, the clock calibration module has two 32-bit counters, one is clocked by the reference clock, and the initial value can be configured as a down counter. The initial value is configured by the register CLKTRIM_REFCON.rcntval, and the counter value can be read from the register CLKTRIM_REFCON. When the counter counts down to 0, it stops counting and generates an interrupt. One is an up-counter that uses the clock to be calibrated as the clock and can configure the overflow value. The overflow value is configured by the register CLKTRIM_CALCON.ccnt_val, and the counter value can be read from the register CLKTRIM_CALCNT. Generate an interrupt.

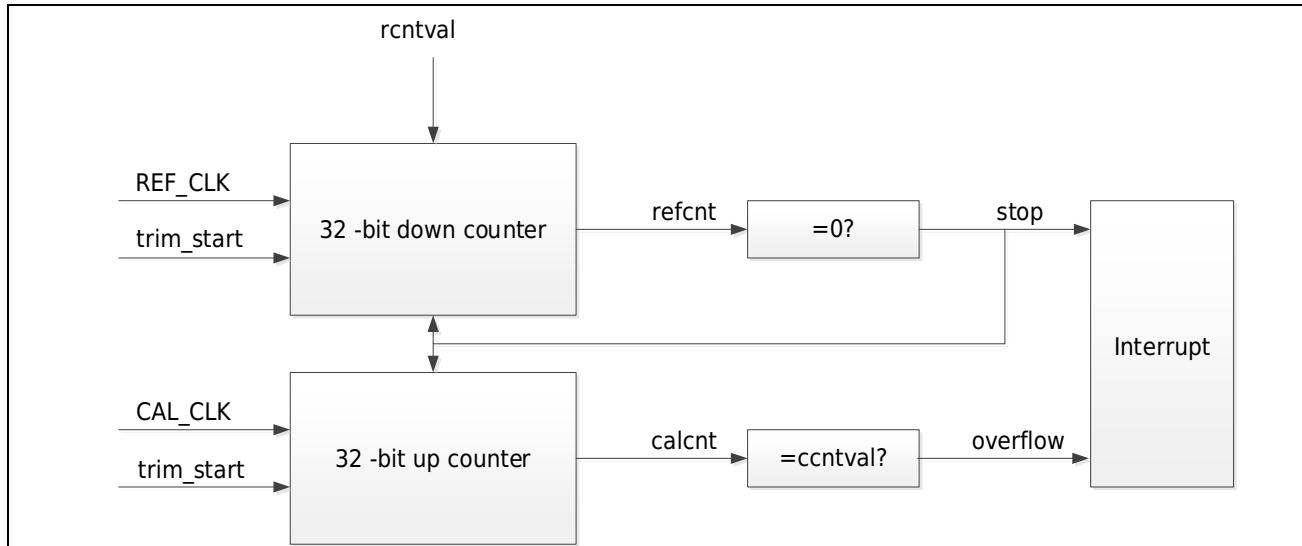

Figure 9-2 Clock Calibration Module Hardware Schematic

9.3.1.3 Clock Calibration Software Flow

1. Set the `CLKTRIM_CR.refclk_sel` register to select the reference clock.
2. Set the `CLKTRIM_CR.calclk_sel` register to select the clock to be calibrated.
3. Set the `CLKTRIM_REFCON.rcntval` register to the calibration time.
4. Set `CLKTRIM_CR.IE` register to enable interrupt.
5. Set the `CLKTRIM_CR.trim_start` register to start the trim.
6. The reference clock counter and the clock to be calibrated counter start counting.
7. When the reference clock counter counts down from the initial value to 0, `CLKTRIM_IFR.stop` is set to 1 and an interrupt is triggered.
8. The interrupt service subroutine judges that `CLKTRIM_IFR.stop` is 1, reads the values of registers `CLKTRIM_REFCNT` and `CLKTRIM_CALCNT`,
9. Clear the `CLKTRIM_CR.trim_start` register to end the trim.
10. Calculate the frequency of the clock to be calibrated according to the formula mentioned in the clock calibration principle chapter,
where $M = \text{value of register } CLKTRIM_CALCNT$,
 $N = \text{value of register } CLKTRIM_REFCON.rcntval$
When the frequency of the clock to be calibrated does not meet the error rate requirements, adjust the parameters of the clock to be calibrated,
Repeat steps 5 to 10 until the clock to be calibrated meets the error rate requirement.

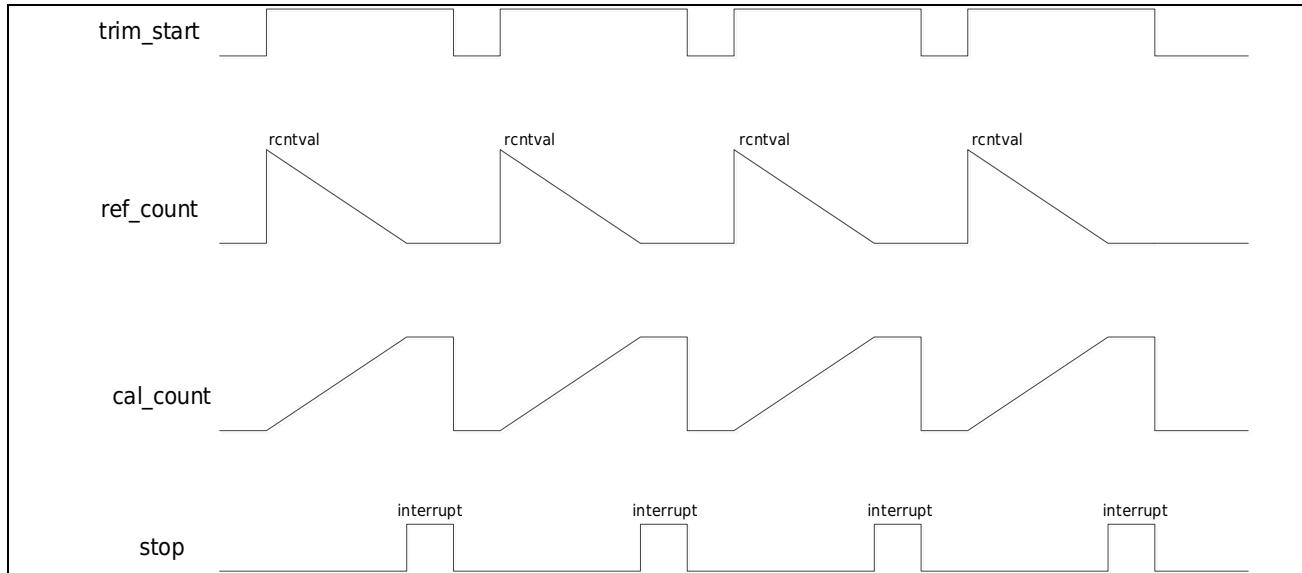

Figure 9-3 Clock Calibration Waveform Diagram

Note:

- In the calibration mode, it is possible that the calibration time is set too long, and the clock counter to be calibrated overflows before CLKTRIM_IFR.stop is set to 1, and CLKTRIM_IFR.calcnt_of is set to 1, triggering an interrupt. When the interrupt service subroutine finds that CLKTRIM_IFR.calcnt_of is set to 1, clear the CLKTRIM_CR.trim_start register to end the calibration.

In this case, the calibration cannot be performed correctly, and the calibration time must be adjusted and re-calibrated.

The specific steps are:

1. Set the CLKTRIM_REFCON.rcntval register to adjust the calibration time.
2. Set the CLKTRIM_CR.trim_start register to restart the trim.

9.3.2 CLKTRIM monitoring mode

9.3.2.1 Clock monitoring principle

In order to monitor whether the system working clock (monitored clock CAL_CLK) is working normally, a stable clock is required as a reference clock (REF_CLK). Set the monitoring time Ttrim, the monitored clock frequency Fcal, the reference clock frequency Fref, the monitored clock counter overflow value CALVAL, use the monitored clock and the reference clock to count at the same time, stop counting when the monitoring time ends, and judge whether the monitored clock counter is in overflow state. If the monitored clock counter has overflowed, it means that the monitored clock works normally within the monitoring time, and the next monitoring is continued. If the counter of the monitored clock does not overflow, it means that the monitored clock is working abnormally within the monitoring time. The monitored clock may have stopped or the frequency has changed

significantly, and the monitored clock is abnormally interrupted, and the system working clock is switched by the hardware.

9.3.2.2 Clock monitoring hardware structure

The monitored clock of the time calibration module has 3 clock sources, and the reference clock has 6 clock sources, as shown in the following figure:

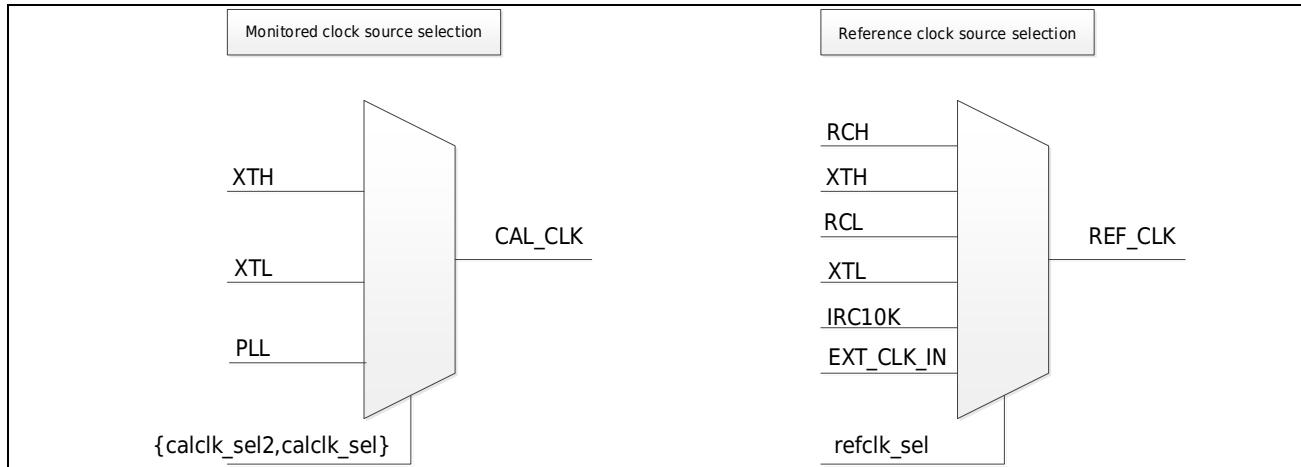

Figure 9-4 CLKTRIM clock selection

The selection of the monitored clock is configured by the register `CLKTRIM_CR.calclk_sel2,CLKTRIM_CR.calclk_sel`, and the selection of the reference clock is configured by the register `CLKTRIM_CR.refclk_sel`.

9.3.2.3 Clock Monitoring Software Flow

1. Set the `CLKTRIM_CR.refclk_sel` register to select the reference clock.
2. Set the `CLKTRIM_CR.calclk_sel` register to select the monitored clock.
3. Set the `CLKTRIM_REFCON.rcntval` register to monitor interval time.
4. Set the `CLKTRIM_CALCON.ccntval` register to the overflow time of the monitored clock counter.
5. Set the `CLKTRIM_CR.mon_en` register to enable the monitor function.
6. Set `CLKTRIM_CR.IE` register to enable interrupt.
7. Set the `CLKTRIM_CR.trim_start` register to start monitoring.
8. The reference clock counter and the monitored clock counter start counting.
9. When the counting of the reference clock counter reaches the monitoring interval time, `CLKTRIM_IFR.stop` is set to 1, and at the same time, it is judged whether the monitored clock counter overflows, that is, whether `CLKTRIM_IFR.calcnt_of` is set to 1. If it overflows, that is, `CLKTRIM_IFR.calcnt_of` is 1, it means that the monitored clock works normally. If there is no overflow, that is, `CLKTRIM_IFR.calcnt_of` is 0, it means that the monitored clock is invalid, and `CLKTRIM_IFR.xtl_fault/xth_fault` is set to 1, triggering an interrupt.
10. Process the interrupt service subroutine, clear the interrupt flag bit `CLKTRIM_IFR.xtl_fault/xth_fault`, and clear the `CLKTRIM_CR.trim_start` register to end

monitoring.

10 Hardware divider module (HDIV)

10.1 Introduction to HDIV

HDIV (Hardware Divider) is a 32-bit signed/unsigned integer hardware divider.

10.2 HDIV main characteristics

The HDIV hardware divider supports the following features:

- Configurable signed/unsigned integer division calculation
- 32-bit dividend, 16-bit divisor
- Output 32-bit quotient and 32-bit remainder
- Divide by zero warning flag, division end flag
- 10 clock cycles to complete a division operation
- Write the divisor register to trigger the start of the division operation
- Automatically wait for the end of the calculation when reading the quotient register/remainder register

10.3 HDIV function description

10.3.1 HDIV operation process

1. Turn on the clock enable register for the hardware divider in the system controller.
2. The configuration register HDIV_SIGN sets signed/unsigned division operation.
3. The configuration register HDIV_DIVIDEND sets the dividend.
4. The configuration register HDIV_DIVISOR sets the divisor.
5. When the division operation starts, query the register HDIV_STAT operation end flag bit div_end, and div_end is 1 to indicate the end of the operation. Read the register HDIV_QUOTIENT to get the quotient, and read the register HDIV_REMAINDER to get the remainder.
6. When the divisor is zero, the division operation ends immediately, and the operation result remains the result of the last operation, and the divisor is zero warning flag bit div_zero is set.
7. Before the end of the division operation, when reading the register HDIV_QUOTIENT/HDIV_REMAINDER, the CPU will be held until the end of the operation.

Example: Calculate an unsigned division, the dividend is 1917887483 (0x7250A3FB), and the divisor is 9597 (0x257D)

Step 1, the configuration register HDIV_SIGN is 0, that is, unsigned division operation

Step 2, configure the register HDIV_DIVIDEND as 0x7250A3FB, that is, set the dividend

Step 3, the configuration register HDIV_DIVISOR is 0x257D, that is, the divisor is set, and the calculation starts

Step 4, query register HDIV_STAT operation end flag div_end, if div_end is 1 flag, the operation ends.

Read the register HDIV_QUOTIENT to get the quotient 199842 (0x30CA2)

Read the register HDIV_REMAINDER to get the remainder 3809 (0xEE1)

11 FLASH controller (FLASH)

11.1 Overview

This system includes a FLASH memory with a capacity of 16k/32k/64k/128k bytes (Byte), which is divided into 32/64/128/256 pages (Sector), and the capacity of each page (Sector) is 512 bytes (Byte). FLASH controller supports erasing, programming and reading operations on the FLASH memory. This controller also supports erasing and writing protection of FLASH memory, and writing protection of control registers.

11.2 FLASH capacity division

Table 11-1 FLASH capacity division

Address	Serial number		Address	Serial number
0x0E00 - 0xFFFF	Sector7	0x1FE00 - 0x1FFFF	Sector255
0x0C00 - 0x0DFF	Sector6	0x1FC00 - 0x1FDFF	Sector254
0x0A00 - 0x0BFF	Sector5	0x1FA00 - 0x1FBFF	Sector253
0x0800 - 0x09FF	Sector4	0x1F800 - 0x1F9FF	Sector252
0x0600 - 0x07FF	Sector3	0x1F600 - 0x1F7FF	Sector251
0x0400 - 0x05FF	Sector2	0x1F400 - 0x1F5FF	Sector250
0x0200 - 0x03FF	Sector1	0x1F200 - 0x1F3FF	Sector249
0x0000 - 0x01FF	Sector0	0x1F000 - 0x1F1FF	Sector248

Note:

- 16KByte FLASH consists of Sector0-32;
- 32KByte FLASH consists of Sector0-63;
- 64KByte FLASH consists of Sector0-127;
- 128KByte FLASH consists of Sector0-255.

11.3 Functional description

This controller supports data read and write operations of three-bit widths of Byte (8 bits), half-word (16 bits) and word (32 bits) of FLASH. Note that the target address of the Byte operation must be byte-aligned, the target address of the half-word operation must be half-word-aligned (the lowest bit of the address is 1'b0), and the address of the word operation must be word-aligned (the lowest two bits of the address are 2'b00). If the target address is not aligned according to the bit width, the operation is invalid and the CPU will enter the Hard Fault interrupt.

This controller adopts high-security hardware design and has the function of FLASH operation source defense: only when the address of the FLASH operation function is located at 0~32K, can the FLASH erase and write operation be performed correctly. FLASH address 0~32K has higher security, important functions must be placed in this area; For example, important program entry,

interrupt entry function, high security algorithm module, UID, AES, true random number algorithm cooperation, to form a high security authentication system.

11.3.1 Sector Erase (Sector Erase)

Sector) specified by the user at a time. After the erase operation is completed, the data in the page (Sector) are all 0xFF. If the erase operation is executed from FLASH, the CPU will stop fetching instructions, and the hardware will automatically wait for the operation to complete (FLASH_CR.BUSY becomes 0); if the erase operation is executed from RAM, the CPU will not stop fetching means, user software should wait for the operation to complete (FLASH_CR.BUSY becomes 0).

Sector erase operation steps are as follows:

Step1: Configure FLASH erasing parameters, see chapter 11.4 for details.

Step2: Write 0x5A5A and 0xA5A5 to the FLASH_BYPASS register in sequence to enable register rewriting.

Step3: Configure FLASH_CR.OP to 2, and set the Flash operation mode to Sector Erase.

Step4: Check whether FLASH_CR.OP is 2, if not, jump to Step2.

Step5: Write 0x5A5A and 0xA5A5 to the FLASH_BYPASS register in sequence to enable register rewriting.

Step6: Set the corresponding bit of FLASH_SLOCK to 1 to remove the sector's erasure protection.

Step7: Check whether the corresponding bit of FLASH_SLOCK is 1, if not, jump to Step5.

Step8: Write arbitrary data to any address in the Sector to be erased, triggering Sector erasure.

Example: * ((unsigned char *) 0x00000200) = 0x00.

Step9: Wait for FLASH_CR.BUSY to become 0, and the Sector erase operation is completed.

Step10: To erase other sectors, repeat Step5 – Step9.

Note:

- The address of the code for page erasing the FLASH must be less than 32768.

11.3.2 Full Chip Erase (Chip Erase)

Full chip erase can erase all pages (Sector) at one time. After the erase operation is completed, the data in all pages (Sector) are 0xFF. If the erase operation is performed from the FLASH, the operation will be prohibited. Because this operation will erase the program segment where the current PC is located. If this happens, the error flag will be set; if the erase operation is performed from RAM, the CPU will not stop fetching instructions, and the user software should wait for the operation to complete (FLASH_CR.BUSY becomes 0).

Chip erase operation steps are as follows:

- Step1: Configure FLASH erasing parameters, see chapter 11.4 for details.
- Step2: Write 0x5A5A and 0xA5A5 to the FLASH_BYPASS register in sequence to enable register rewriting.
- Step3: Configure FLASH_CR. OP to 3, and set the Flash operation mode to Chip erase.
- Step4: Check whether FLASH_CR.OP is 3, if not, jump to Step2.
- Step5: Write 0x5A5A and 0xA5A5 to the FLASH_BYPASS register in sequence to enable register rewriting.
- Step6: Set FLASH_SLOCK0 to 0xFFFFFFFF to remove the erase and write protection of all Sectors.
- Step7: Check if FLASH_SLOCK0 is 0xFFFFFFFF, if not 0xFFFFFFFF, jump to Then jump to Step5.
- Step8: Write 0x5A5A and 0xA5A5 to the FLASH_BYPASS register in sequence to enable register rewriting.
- Step9: Set FLASH_SLOCK1 to 0xFFFFFFFF to remove the erase and write protection of all Sectors.
- Step10: Check whether FLASH_SLOCK1 is 0xFFFFFFFF, if it is not 0xFFFFFFFF, jump to Then jump to Step8.
- Step11: Write any address in the Chip to be erased to trigger Chip erasure.

Example: * ((unsigned char *) 0x00000000) = 0x00.

Step12: Wait for FLASH_CR. BUSY to become 0, and the Chip erase operation is completed.

11.3.3 Write operation (Program)

The write operation can only change the bit data in FLASH from 1 to 0, so before writing data, make sure that the data in the address to be written is 0xFF. Support writing 3 data lengths: Byte (8bits), Half-word (16bits), Word (32bits). The written data is stored in FLASH in little-endian mode, that is, the low byte of the data is stored in the low address. If the write operation is executed from FLASH, the CPU will stop fetching instructions, and the hardware will automatically wait for the operation to complete (FLASH_CR. BUSY becomes 0); if the write operation is executed from RAM, the CPU will not stop fetching instructions, and the user Software should wait for the operation to complete (FLASH_CR. BUSY goes to 0).

Byte write operation steps are as follows:

- Step1: Configure FLASH erasing parameters, see chapter 11.4 for details.
- Step2: Write 0x5A5A and 0xA5A5 to the FLASH_BYPASS register in sequence to enable register rewriting.
- Step3: Configure FLASH_CR. OP to 1, and set the Flash operation mode to write.
- Step4: Check whether FLASH_CR.OP is 1, if not, jump to Step2.

Step5: Write 0x5A5A and 0xA5A5 to the FLASH_BYPASS register in sequence to enable register rewriting.

Step6: Set the corresponding bit of FLASH_SLOCK to 1 to remove the erase protection.

Step7: Check whether the corresponding bit of FLASH_SLOCK is 1, if it is not 1, jump to Step5.

Step8: Perform Byte write operation on the target address to be written to trigger the write operation.

Example: * ((unsigned char *) 0x00001231) = 0x5A.

Step9: Wait for FLASH_CR. BUSY to become 0, and the write operation is completed.

Step10: To write Byte to other addresses, repeat Step8 - Step9.

Half-word write operation steps are as follows:

Step1: Configure the flash erasing time, see chapter 11.4 for details.

Step2: Write 0x5A5A and 0xA5A5 to the FLASH_BYPASS register in sequence to enable register rewriting.

Step3: Configure FLASH_CR. OP to 1, and set the Flash operation mode to write.

Step4: Check whether FLASH_CR.OP is 1, if not, jump to Step2.

Step5: Write 0x5A5A and 0xA5A5 to the FLASH_BYPASS register in sequence to enable register rewriting.

Step6: Set the corresponding bit of FLASH_SLOCK to 1 to remove the erase protection.

Step7: Check whether the corresponding bit of FLASH_SLOCK is 1, if not, jump to Step5.

Step8: Perform a Half-word write operation on the target address to be written to trigger the write operation.

Example: * ((unsigned short int *) 0x00001232) = 0xABCD.

Step9: Wait for FLASH_CR. BUSY to become 0, and the write operation is completed.

Step10: To write Half-word to other addresses, repeat Step8 - Step9.

Word write operation steps are as follows:

Step1: Configure FLASH erasing parameters, see chapter 11.4 for details.

Step2: Write 0x5A5A and 0xA5A5 to the FLASH_BYPASS register in sequence to enable register rewriting.

Step3: Configure FLASH_CR. OP to 1, and set the Flash operation mode to write.

Step4: Check whether FLASH_CR.OP is 1, if not, jump to Step2.

Step5: Write 0x5A5A and 0xA5A5 to the FLASH_BYPASS register in sequence to enable register rewriting.

Step6: Set the corresponding bit of FLASH_SLOCK to 1 to remove the erase protection.

Step7: Check whether the corresponding bit of FLASH_SLOCK is 1, if not, jump to Step5.

Step8: Perform a Word write operation on the target address to be written to trigger the write operation.

Example: * ((unsigned int *) 0x00001234) = 0x55667788.

Step9: Wait for FLASH_CR. BUSY to become 0, and the write operation is completed.

Step10: If you need to write Word to other addresses, repeat Step8 - Step9.

Note:

- **The address of the code that writes to FLASH must be less than 32768.**

11.3.4 Read operation (Read)

Support to read 3 data lengths: Byte (8bits), Half-word (16bits), Word (32bits), the read data is little-endian mode, that is, the low byte of the data stored in the low address. the data in the FLASH can be read at any time.

example:

Byte read operation: *temp = * ((unsigned char *) 0x00001231)*

Half-word read operation: *temp = * ((unsigned short int *) 0x00001232)*

Word read operation: *temp = * ((unsigned int *) 0x00001234)*

11.4 Erase time

FLASH memory has strict time requirements for the control signals of the erasing and programming operations, and failure of the timing of the control signals will cause the erasing and programming operations to fail. When powering on, the erasing parameters when HCLK is 4MHz are loaded by default; if the HCLK frequency is not 4MHz when erasing Flash, the user program should load the erasing parameters corresponding to the HCLK frequency. When operating on FLASH, the highest supported HCLK is 48MHz.

The registers related to the erasing timing parameters are: FLASH_TNVS, FLASH_TPGS, FLASH_TPROG, FLASH_TSERASE, FLASH_TMERASE, FLASH_TPRCV, FLASH_TSRCV, FLASH_TMRCV. If the HCLK is increased from the default 4MHz to 8MHz, the value of the above FLASH_Tx register should be set to twice the default value, that is, keep the current result of Tsysclk*FLASH_Tx equal to the default value.

The following table shows the corresponding FLASH erasing time parameters at different frequencies:

Table 11-2 FLASH erasing time parameters at different frequencies

Parameter	4M	8M	16M	24M	32M	48M
TNVS	0x20	0x40	0x80	0xC0	0x100	0x180
TPGS	0x17	0x2E	0x5C	0x8A	0xB8	0xFF
TPROG	0x1B	0x36	0x6C	0xA2	0xD8	0x144
TSERASE	0x4650	0x8CA0	0x11940	0x1A5E0	0x23280	0x34BC0
TMERASE	0x222E0	0x445C0	0x88B80	0xCD140	0x111700	0x19A280
TPRCV	0x18	0x30	0x60	0x90	0xC0	0x120
TSRCV	0xF0	0x1E0	0x3C0	0x5A0	0x780	0xB40
TMRCV	0x3E8	0x7D0	0xFA0	0x1770	0x1F40	0x2EE0

The operation steps to configure the erasing and writing parameters when the system frequency is 8MHz are as follows:

Step1: Write 0x5A5A and 0xA5A5 to the FLASH_BYPASS register in sequence to enable register rewriting.

Step2: Write 0x40 to the FLASH_TNVS register, if the read value of this register is not 0x40, then jump to the previous step.

Step3: Write 0x5A5A and 0xA5A5 to the FLASH_BYPASS register in sequence to enable register rewriting.

Step4: Write 0x2E to the FLASH_TPGS register, if the read value of this register is not 0x2E, then jump to the previous step.

Step5: Write 0x5A5A and 0xA5A5 to the FLASH_BYPASS register in sequence to enable register rewriting.

Step6: Write 0x36 to the FLASH_TPROG register, if the read value of this register is not 0x36, then jump to the previous step.

Step7: Write 0x5A5A and 0xA5A5 to the FLASH_BYPASS register in sequence to enable register rewriting.

Step8: Write 0x8CA0 to the FLASH_TSERASE register, if the read value of this register is not 0x8CA0, then jump to the previous step.

Step9: Write 0x5A5A and 0xA5A5 to the FLASH_BYPASS register in sequence to enable register rewriting.

Step10: Write 0x445C0 to the FLASH_TMERASE register, if the read value of this register is not 0x445C0, then jump to the previous step.

Step11: Write 0x5A5A and 0xA5A5 to the FLASH_BYPASS register in sequence to enable register rewriting.

Step12: Write 0x30 to the FLASH_TPRCV register, if the read value of this register is not 0x30, then jump to the previous step.

Step13: Write 0x5A5A and 0xA5A5 to the FLASH_BYPASS register in sequence to enable register rewriting.

Step14: Write 0x1E0 to the FLASH_TSRCV register, if the read value of this register is not 0x1E0, then jump to the previous step.

Step15: Write 0x5A5A and 0xA5A5 to the FLASH_BYPASS register in sequence to enable register rewriting.

Step16: Write 0x7D0 to the FLASH_TMRCV register, if the read value of this register is not 0x7D0, then jump to the previous step.

11.5 Read wait period

The fastest instruction fetch frequency supported by the built-in FLASH of this device is 24MHz. When the HCLK frequency exceeds 24MHz and is less than 48MHz, a waiting period must be inserted for the FLASH read time, that is, set FLASH_CR.WAIT to 1. When the wait cycle is inserted, FLASH will complete a read operation every two cycles.

11.6Erase and write protection

11.6.1 Erase and write protection bit

The entire 16k/32k/64k/128k byte FLASH memory is divided into 32/64/128/256 pages, and every 4 pages share an erase/write protection bit. When the page is protected, the erasing and writing operations on the page are invalid and an alarm flag and interrupt signal are generated. When any page in the FLASH memory is protected, the whole-chip erasing of the FLASH is invalid, and an alarm flag and an interrupt signal are generated.

11.6.2 PC address erase and write protection

The CPU runs the program in FLASH, if the current PC pointer just falls within the address range of the page to be erased, then the erase operation is invalid and an alarm flag and an interrupt signal are generated.

11.7Register write protection

The important controller of this module shields ordinary write operations, and must be modified by writing sequence.

Registers that require a write sequence to be changed are as follows:

FLASH_TNVS, FLASH_TPGS, FLASH_TPROG, FLASH_TSERASE, FLASH_TMERASE, FLASH_TPRCV,
FLASH_TSRCV, FLASH_TMRCV, FLASH_CR, FLASH_SLOCK0, FLASH_SLOCK1.

Registers that can be changed without a write sequence are as follows:

FLASH_ICLR, FLASH_BYPASS.

The specific operation steps to modify the register value by writing sequence are as follows:

Step1: Write 0x5A5A to the FLASH_BYPASS register.

Step2: Write 0xA5A5 to the FLASH_BYPASS register.

Step3: Write the target value to the register to be modified.

Step4: Verify whether the current value of the register to be modified is the same as the target, if not, jump to Step1.

Step5: Perform other operations.

Note:

- Write 0x5a5a, 0xa5a5, and write the target register. Do not insert any write operations (write ROM, RAM, REG) between these three steps of writing operations, otherwise the value of the target register cannot be rewritten. If rewriting fails, you need to perform these three steps again.

11.8 Register

Base address: 0x4002 0000

Register	Offset address	Description
FLASH_TNVS	0x00	Tnvs time parameter
FLASH_TPGS	0x04	Tpgs time parameter
FLASH_TPROG	0x08	Tprog time parameter
FLASH_TSERASE	0x0C	Tserase time parameter
FLASH_TMERASE	0x10	Tmerase time parameter
FLASH_TPRCV	0x14	Tprcv time parameter
FLASH_TSRCV	0x18	Tsrcv time parameters
FLASH_TMRCV	0x1C	Tmrcv time parameter
FLASH_CR	0x20	control register
FLASH_IFR	0x24	Interrupt Flag Register
FLASH_ICLR	0x28	Interrupt Flag Clear Register
FLASH_BYPASS	0x2C	0x5a5a-0xa5a5 Bypass sequence register
FLASH_SLOCK0	0x30	Sector0-127 erase and write protection register
FLASH_SLOCK1	0x34	Sector128-255 erase and write protection register

11.8.1 TNVS parameter register (FLASH_TNVS)

Offset address: 0x00

Reset value: 0x0000 0020

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								TNVS

12 RAM controller (RAM)

12.1 Overview

This system includes a SRAM with a capacity of 2k/4k/8k/16k bytes (Byte), which supports three kinds of read and write operations: byte (8 bits), half word (16 bits), and word (32 bits). Read and write operations can be performed at the system clock frequency without waiting for cycles. In addition, this controller also supports parity check, which can perform parity check on each byte (Byte) of SRAM data, and generate a parity check error interrupt.

12.2 Functional description

12.2.1 RAM address range

RAM in the system map is shown in the table below:

Table 12-1 RAM Address Mapping

Address range	Size	Memory type
0x2000_0000 - 0x2000_3FFF	16KByte	SRAM

12.2.2 Read and write bit width

This controller supports Byte (8 bits), halfword (16 bits), word (32 bits) Read and write operations with three-bit widths. The address of the byte operation must be byte-aligned, the target address of the half-word operation must be half-word-aligned (the lowest bit of the address is 1'b0), the address of the word operation must be word-aligned (the lowest two bits of the address are 2'b00). If the target address of the read and write operation is not aligned according to the bit width, the operation is invalid, and the system will generate a Hard Fault error interrupt.

12.2.3 Parity

This controller supports parity check of SRAM data. When writing data to SRAM, do a parity check on each byte of data, and store the 1-bit check value and 8-bits data into the SRAM together. When reading data from SRAM, the controller will read 8bits data and 1bit check value, and perform parity check. If the check is wrong, the parity check error flag will be set. When the interrupt is enabled, a Error interrupt.

Note:

- When the parity check is enabled, the SRAM must be initialized before reading the SRAM data, otherwise the parity check alarm flag or interrupt may be triggered by mistake.

12.3 Register

13 DMA controller DMAC

13.1 Introduction to DMAC

Direct memory access (DMA) is used to provide high-speed data transmission between peripherals and memory or between memory and memory; the CPU does not need to participate in the transmission process; so the CPU can perform other operations synchronously. The DMAC has two independent DMA channels, each channel is dedicated to managing requests from peripherals or memory access. There is also an arbiter to coordinate the priority of each DMA request.

13.2 DMAC main characteristics

- 2 independent DMA channels, support priority configuration
- 3 data transfer widths: 8-bit, 16-bit, 32-bit
- 4 transmission modes: Software Block, Software Burst, Hardware Block, Hardware Burst
- 2 source address types: peripheral, memory
- 2 target address types: peripheral, memory
- 2 address change modes: fixed, auto-increment
- Transmission address addressing range: 0x00000000 ~ 0xFFFFFFFF
- The number of data blocks to be transmitted is configurable: 1~65536
- The size of the data block to be transmitted is configurable: 1~16
- Support address and transfer number reload function

13.3 Functional block diagram

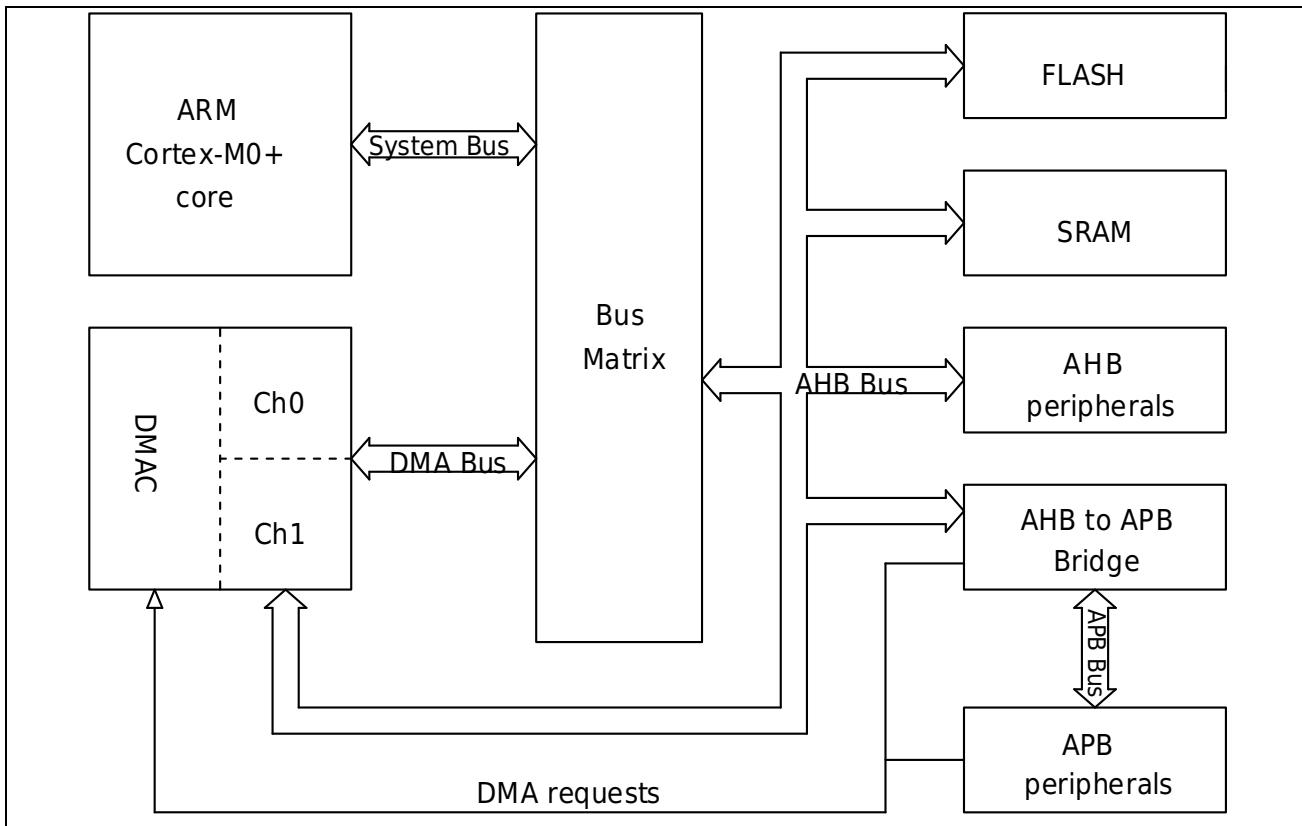

Figure 13-1 Functional block diagram

- DMAC
 - The DMAC has two DMA channels, and when conflicts occur between channels, the priority controller conducts arbitration.
- Bus Matrix
 - CPU and DMAC are connected to the bus matrix. When the CPU releases the AHB bus, the DMAC can access the AHB bus device and the APB bus device through the Bus Matrix. The priority of CPU accessing the bus is higher than that of DMAC.
- DMA requests
 - If the peripheral supports DMA request, the DMA channel can be configured as a hardware trigger, otherwise it can only be configured as a software trigger.

13.4 Functional description

13.4.1 DMAC transfer modes

The DMA controller supports 4 transfer modes, software Block transfer mode, software Burst transfer mode, hardware Block transfer mode, and hardware Burst transfer mode.

The 4 transmission modes is shown in the table below:

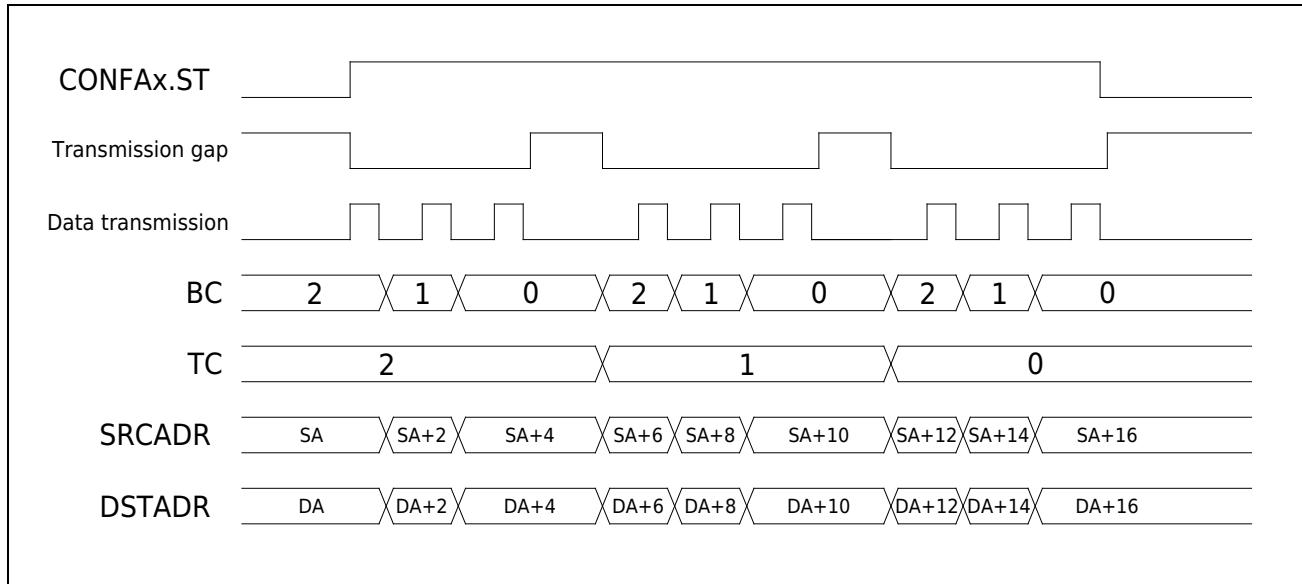

Compare Items	Software Block Transmission	Software Burst Transmission	Hardware Block Transmission	Hardware Burst Transmission
Interrupted by higher priority DMA channel or CPU	Can	Can't	Can	Can't
Conditions that trigger the start of the transfer	Write DMAC Register		Peripheral interrupt flag	
The amount of data that triggers a transfer	$(BC+1) * (TC+1)$		BC+1	$(BC+1) * (TC+1)$
The total amount of data transferred after configuration			$(BC+1) * (TC+1)$	
Main application scenarios	<ul style="list-style-type: none"> • Memory to memory • Memory to peripherals without DMA requests 		<ul style="list-style-type: none"> • Memory to peripherals with DMA requests • With DMA requests to memory 	<ul style="list-style-type: none"> • Memory to memory • Memory to peripherals without DMA requests

13.4.2 DMA software block transfer mode

When configuring DMAC_CONFAx.TRI_SEL=0 and DMAC_CONFBx.MODE=0, DMAC works in software Block transfer mode.

When the user code writes 1 to DMAC_CONFAx.ST, the DAMC is triggered to start the software Block transfer mode; the DMA transfer stops after completing $(BC+1) * (TC+1)$ data. Each transmission of BC+1 data is completed, the DMAC inserts a transmission gap, and the priority arbiter performs priority arbitration in the gap. The CPU or a higher priority DMA channel requests the bus during this gap, the bus ownership is transferred to the CPU or a higher priority DMA channel; when the CPU or a higher priority DMA channel releases the bus, the unfinished data transfer will continue to be completed.

The software Block transmission diagram is shown below, where SA represents the source address and DA represents the target address; The size of the data block is 3 (BC=2), the number of data blocks is 3 (TC=2), the data width is 16bit, and the address increases automatically.

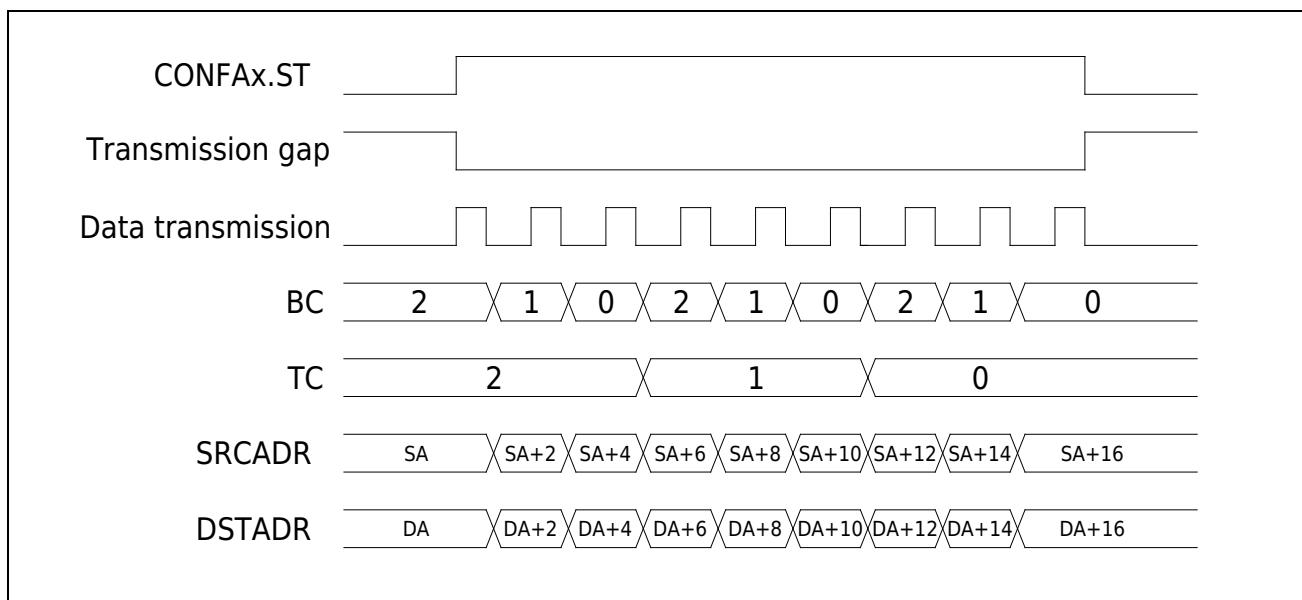

13.4.3 DMA software Burst transfer mode

When configuring DMAC_CONFAx.TRI_SEL=0 and DMAC_CONFBx.MODE=1, DMAC works in software Burst transfer mode.

When the user code writes 1 to DMAC_CONFAx.ST, the DMAC is triggered to start the software Burst transfer mode; the DMA transfer stops after completing $(BC+1) * (TC+1)$ data. The DMA will occupy the bus until all data transfers are completed, and the CPU or a higher-priority DMA channel can only access the bus after the operation is completed. The CPU may not work completely for a period of time.

The software Burst transmission diagram is as follows, where SA represents the source address, DA represents the destination address; the data block size is 3 (BC=2), the number of data blocks is 3 (TC=2), the data width is 16bit, and the address is self-incrementing.

13.4.4 DMA hardware block transfer mode

When configuring DMAC_CONFAx.TRI_SEL= non-zero and DMAC_CONFbx.MODE=0, DMAC works in hardware Block transfer mode.

Whenever the peripheral DMA request signal appears once, the DMAC is triggered to start a hardware block transfer, and transfer (BC+1) data. It needs to appear (TC+1) peripheral DMA request signal to complete the transmission of all DMA data. Every BC+1 data is completed, the DMAC inserts a transmission gap, and the priority arbiter performs priority arbitration in the gap. The CPU or a higher priority DMA channel is also requesting the bus during this gap, the bus ownership is transferred to the CPU or a higher priority DMA channel; when the CPU or a higher priority DMA channel releases the bus, the unfinished data transfer will continue Finish.

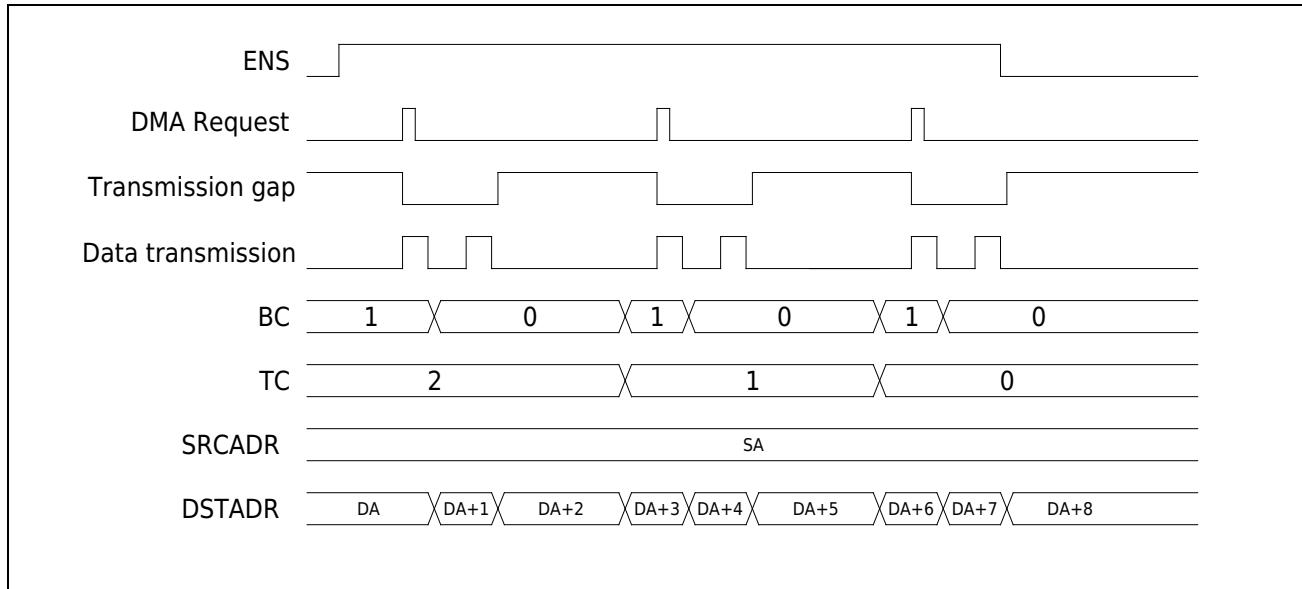

Note:

- **In this mode, generally set BC to 0 to obtain a data from the peripheral or provide a data to the peripheral.**

Request signals supported by DMA are as follows:

- LPUARTx / UARTx receiving Buf is not empty, sending Buf is empty
- SPIx receiving Buf is not empty, sending Buf is empty
- I2Sx receiving Buf is not empty, sending Buf is empty
- TIMx capture complete, comparison match
- ADC queue conversion completed
- ADC sequential conversion complete
- DAC conversion complete

The hardware block transmission diagram is as follows, where SA represents the source address, DA represents the target address; the data block size is 2 (BC=1), the number of data blocks is 3 (TC=2), the data width is 8bit, and the target address is self-incrementing, the source address is fixed, and the transmission is automatically disabled after completion.

13.4.5 DMA hardware Burst transfer mode

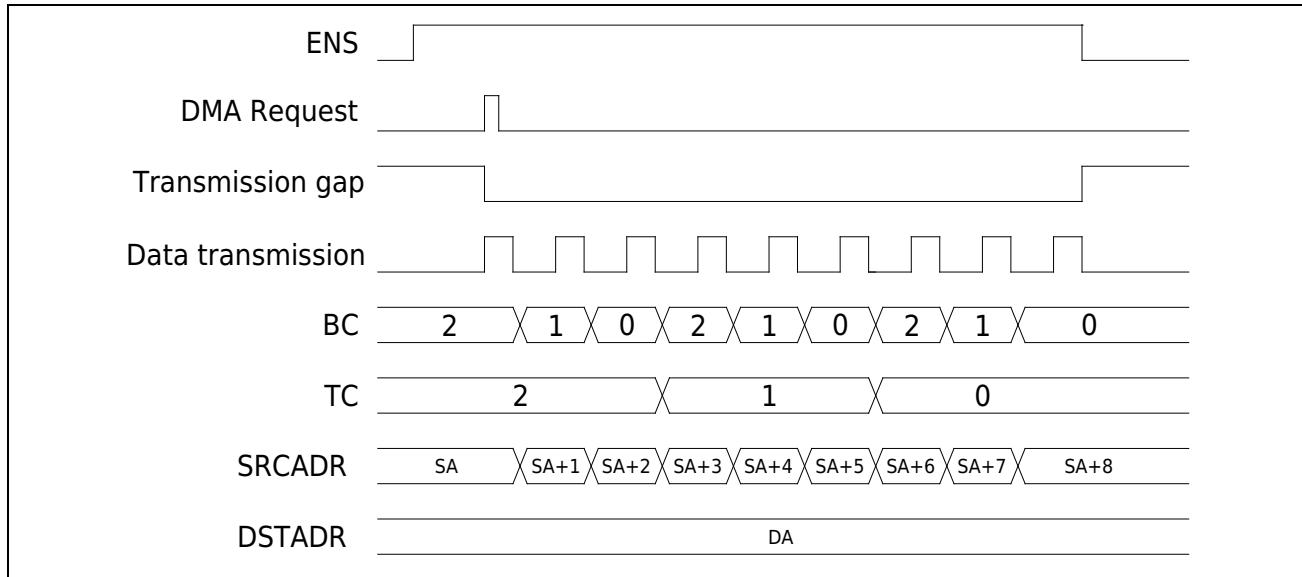

When configuring `DMAC_CONFAX.TRI_SEL= non-zero` and `DMAC_CONFBx.MODE=1`, DMAC works in hardware Burst transfer mode.

When the peripheral DMA request signal appears, the DMAC is triggered to start the hardware Burst transmission mode, and stops after the transmission is completed $(BC+1) * (TC+1)$ data. The DMA will occupy the bus until all data transfers are completed, and the CPU or a higher-priority DMA channel can only access the bus after the operation is completed. The CPU may not work completely for a period of time.

Request signals supported by DMAC are as follows:

- LPUARTx / UARTx receiving Buf is not empty, sending Buf is empty
- SPIx receiving Buf is not empty, sending Buf is empty
- I2Sx receiving Buf is not empty, sending Buf is empty
- TIMx capture complete, comparison match
- ADC queue conversion completed
- ADC sequential conversion complete
- DAC conversion complete

The hardware Burst transmission diagram is as follows, where SA represents the source address, DA represents the target address; the data block size is 3 ($BC=2$), the number of data blocks is 3 ($TC=2$), the data width is 8bit, and the source address is auto-incremented, the target address is fixed, and the transfer is automatically disabled after completion.

13.4.6 DMA transfer paused

When DMAC works in Block transfer mode, if DMAC_CONF.HALT is set to a non-zero value, all channels that are being transferred will enter the pause state during the transfer interval, and no more data transfer will be performed. When DMAC_CONFAx.PAS is configured as 1, the channel corresponding to x that is being transmitted will enter a pause state during the transmission interval, and no data transmission will be performed. DMAC_CONFAx.PAS is configured as 1, the channel corresponding to x that is being transmitted will enter a pause state during the transmission interval and no longer transmit data. configuring DMAC_CONFAx.PAS to 0, DMAC needs to receive the next trigger signal before continuing the unfinished transmission.

When the DMAC works in the Burst transfer mode and no data transfer is performed, configure DMAC_CONF.HALT to a non-zero value, and the DMA channel enters the pause state and no longer performs data transfer. After configuring DMAC_CONF.HALT to 0, DMAC will start a new complete transmission when it receives the next trigger signal. When the DMAC works in the Burst transfer mode and no data transfer is performed, when DMAC_CONFAx.PAS is set to 1, the DMA channel enters the pause state and no data transfer is performed. After configuring DMAC_CONFAx.PAS to 0, DMAC will start a new complete transmission when it receives the next trigger signal.

When the DMAC is working in the Burst transfer mode and data transfer is in progress, writing a non-zero value to DMAC_CONF.HALT or writing 1 to DMAC_CONFAx.PAS cannot pause the ongoing transfer; the DMA channel will not enter the pause after the current transfer is completed state.

13.4.7 DMA other configuration

13.4.7.1 Data width

Configure DMAC_CONFBx.WIDTH, you can configure the width of each data to be transmitted as 8bit, 16bit, 32bit, note that the bit width should be completely consistent with the bit width of the DMA source address and target address.

13.4.7.2 Block size

Configure DMAC_CONFAX.BC, you can configure the number of data to be transmitted in each data block as 1~16. Note that the value of BC should match the number of consecutive operations provided by the source and destination addresses.

If the source address or destination address can only provide or receive one data at a time, then BC can only be configured as 0. For example, UART/LPUART/SPI can only provide one data to DMA each time, and UART/LPUART/SPI/DAC can only receive one data from DMA each time, so BC can only be configured as 0.

If both the source address and the destination address can provide or receive multiple data, BC can be configured to a larger value to speed up the transmission speed. For example, when transferring from FLASH to RAM or from FLASH to CRC, the source address and target address can be operated continuously, so BC can be configured as 15 to achieve fast transfer.

13.4.7.3 Number of data blocks

Configure DMAC_CONFAX.TC, you can configure the number of data blocks to be transferred from 1 to 65536 after each DMA is started.

13.4.7.4 channel priority

When DMAC_CONF.PRIO=0, DMAC works in fixed priority mode. At this time, CH0 has a higher priority than CH1, and only when CH0 does not perform data transmission, CH1 can perform data transmission.

When DMAC_CONF.PRIO=1, DMAC works in cycle priority mode. At this time, CH0 and CH1 have higher priority in turn, and the two channels will occupy the bus in turn for data transmission.

13.4.7.5 Auto reload

If the automatic reload function is enabled, the data block size, number of data blocks, source address, and destination address will be automatically loaded to the last configuration value after the transmission is completed, and there is no need to configure it every time.

13.4.8 DMA interrupt

DMA supports two types of interrupts: transfer error and transfer complete. When an interrupt is triggered, the status register DMAC_CONFBx.STAT can be checked to determine what condition

triggered the interrupt, and the built-in interrupt status flag can be cleared by clearing the register DMAC_CONFBx.STAT.

The five conditions that trigger the DMA interrupt are as follows:

- Transport address out of addressing range
- Peripheral request to stop DMA
- Error accessing the transfer source address
- Access transfer destination address error
- Transmission completion

14 General purpose timer (TIM0/1/2/3)

14.1 Introduction to General-Purpose Timers

TIM0/1/2 is a timer composed of 1 counting unit and 2 comparing units respectively. Each timer supports 2 independent PWM outputs or 1 pair of complementary PWM outputs and 1 independent PWM output. Supports 2 capture inputs. TIM0/1/2 can form 3 pairs of complementary PWM output.

TIM3 is a timer composed of 1 counting unit and 6 comparison units, and supports 6 independent PWM outputs or 3 pairs of complementary PWM outputs. Supports 6 capture inputs.

Using timer prescaler, system prescaler and system clock selection, the pulse width and waveform period can be flexibly adjusted; the pulse width can be measured conveniently.

14.1.1 Basic Features (TIM0/1/2)

- 2 independent PWM outputs CHA, CHB,
- 1 channel complementary PWM output (CHA, CHB) + 1 channel independent PWM output (gate)
- 1 channel complementary PWM output (CHA, CHB) + 1 channel capture function (gate)
- Up to 2 capture inputs
- Pulse Width Measurement
- Dead zone control
- Brake control
- Edge alignment, symmetric center alignment and asymmetric center alignment PWM output
- Quadrature code counting function
- Single pulse mode
- External counting function
- DMA trigger
- When the system clock selects PLL, the timer clock can be configured as twice the frequency of the system clock

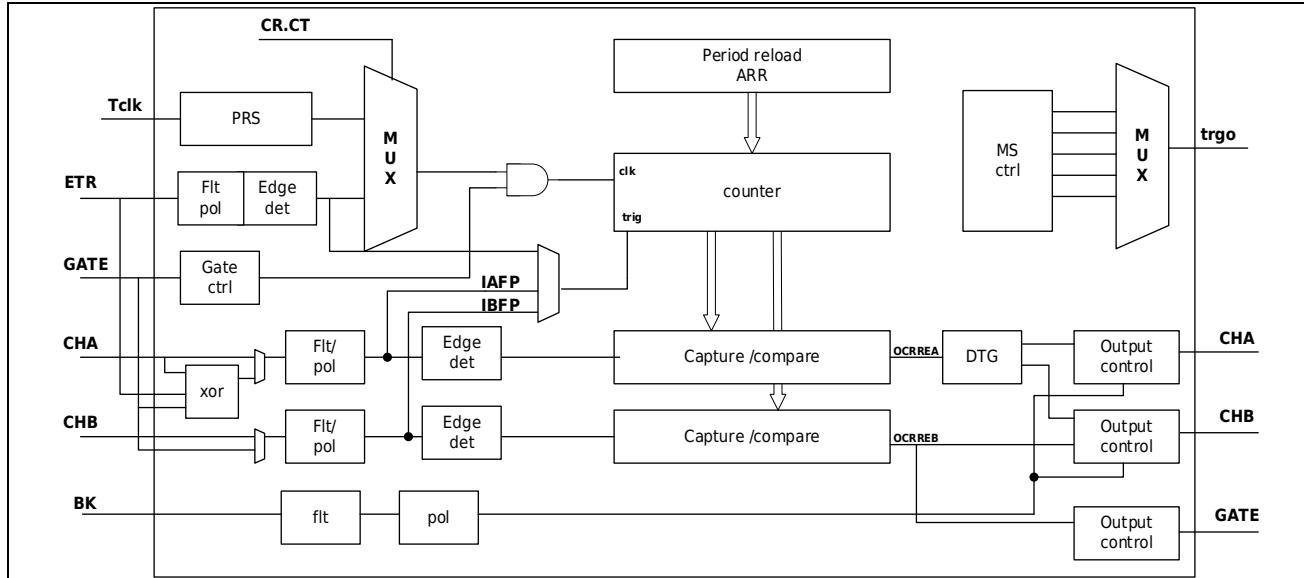

Figure 14-1 TIM0/1/2 block diagram

14.1.2 Basic Features (TIM3)

- 6 independent PWM outputs CH0A, CH0B, CH1A, CH1B, CH2A, CH2B
- 3 complementary PWM outputs (CHxA, CHxB) + 1 independent PWM output (gate)
- 3-way complementary PWM output (CHxA, CHxB) + 1 -way capture function (gate)
- Up to 6 capture inputs
- Pulse Width Measurement
- Dead zone control
- Brake control
- Edge alignment, symmetric center alignment and asymmetric center alignment PWM output
- Quadrature code counting function
- Single pulse mode
- External counting function
- DMA trigger
- When the system clock selects PLL, the timer clock can be configured as twice the frequency of the system clock

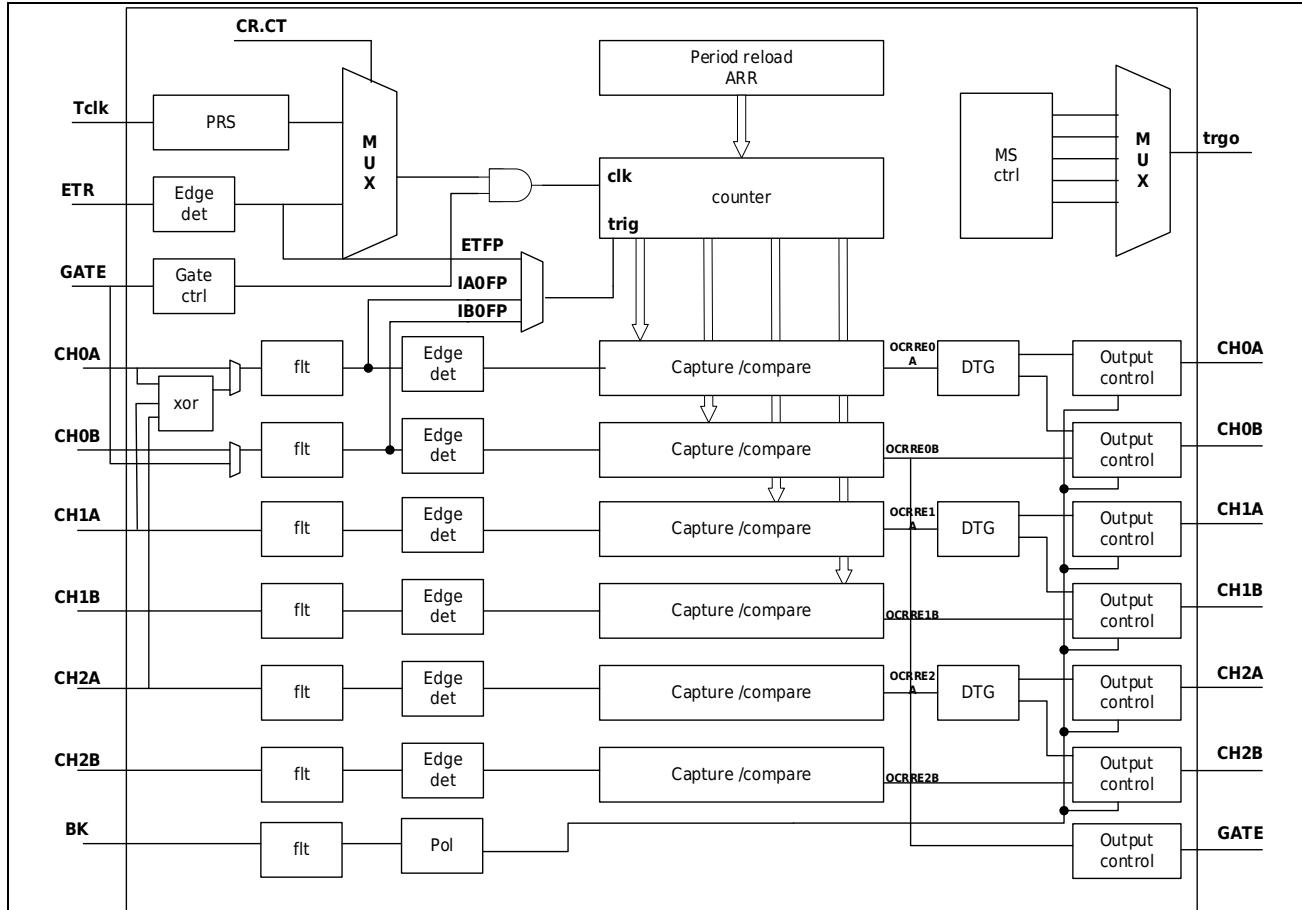

Figure 14-2 TIM3 block diagram

14.2 Timer function description

14.2.1 Timer clock

The timer uses PCLK as the timer clock, and the timer clock is marked with TCLK below.

14.2.2 Timer counter

The main building block of the programmable general-purpose timer is a 16-bit counter and its associated auto-reload register. The counter can count up, count down, or alternately count up and down. The counter clock can be divided by a prescaler.

The counter, auto-reload register and prescaler register can be read and written by software. Read and write operations can be performed even while the counter is running.

14.2.3 Timer Prescaler

Using TCLK as the timer clock, prescaler can be used. The prescaler settings are as follows:

PRS	000	001	010	011	100	101	110	111
Frequency division ratio	1	2	4	8	16	32	64	256

The prescaler does not have a preloaded buffer, so any changes to the prescaler will take effect immediately.

14.2.4 Mode 0 count timer function

In this mode, the counter counts up. The counter supports two counting modes, reload mode and free counting mode, and you can choose external clock ETR counting or system clock counting. The gate control gate can control the count mask. Counting to the maximum overflow generates an interrupt. Invert the output port CHA, CHB, in this mode, CHA, CHB are reversed.

The counting range of the reload mode counts up from ARR to 0xFFFF overflow, and then starts counting from ARR, and the counting period is 0Xffff-ARR+1; the free counting mode overflows after counting from the set count value to 0xFFFFFFFF, and the count value restarts from 0x0 after overflow count.

The counter can be used to control whether the counter counts through the external gate control function. The control relationship is as follows:

M0CR.GATE	M0CR.GATEP	Port GATE input	M0CR.CTEN	Counter
x	x	x	0	Not count
0	x	x	1	Count
1	0	High level	1	Count
1	0	Low level	1	Not count
1	1	High level	1	Not count
1	1	Low level	1	Count

14.2.4.1 Functional block diagram

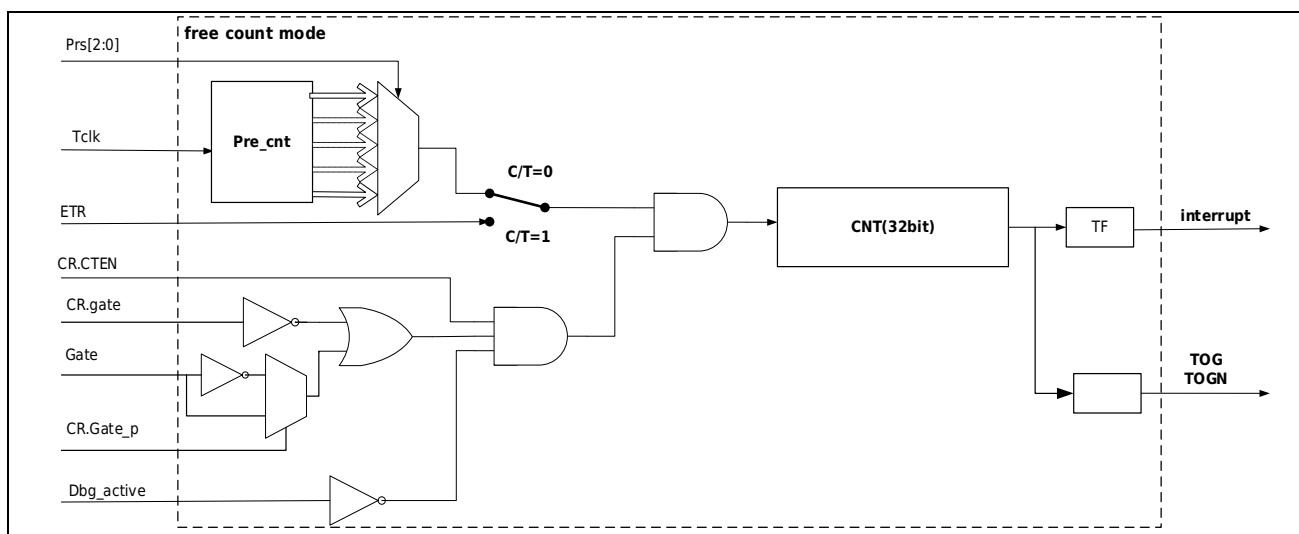

Figure 14-3 Free Counting Block Diagram

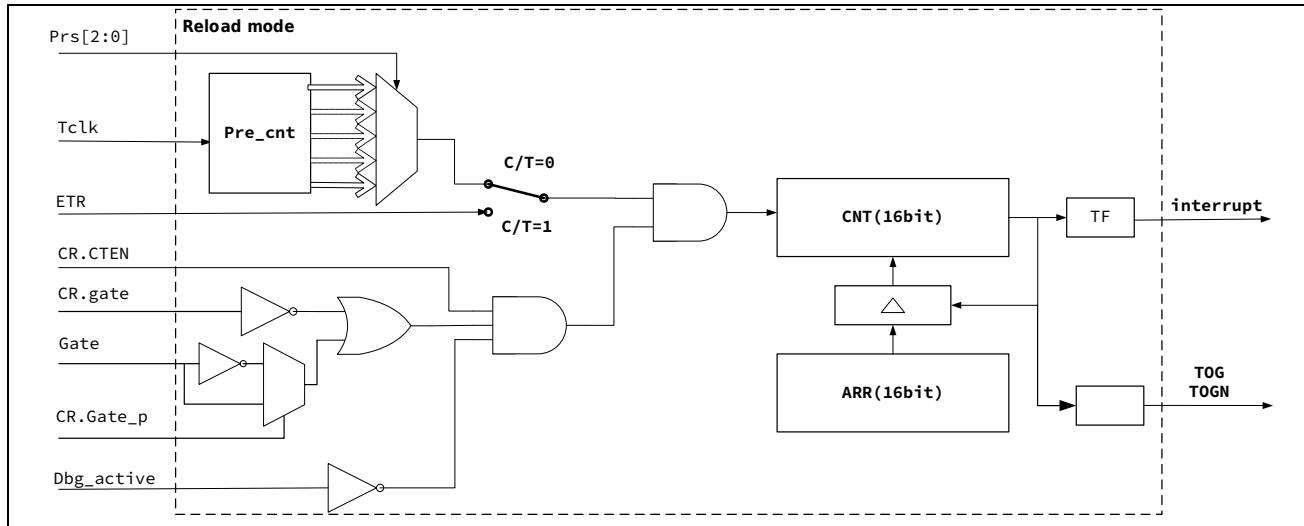

Figure 14-4 Heavy Duty Counting Waveform

14.2.4.2 Count waveform

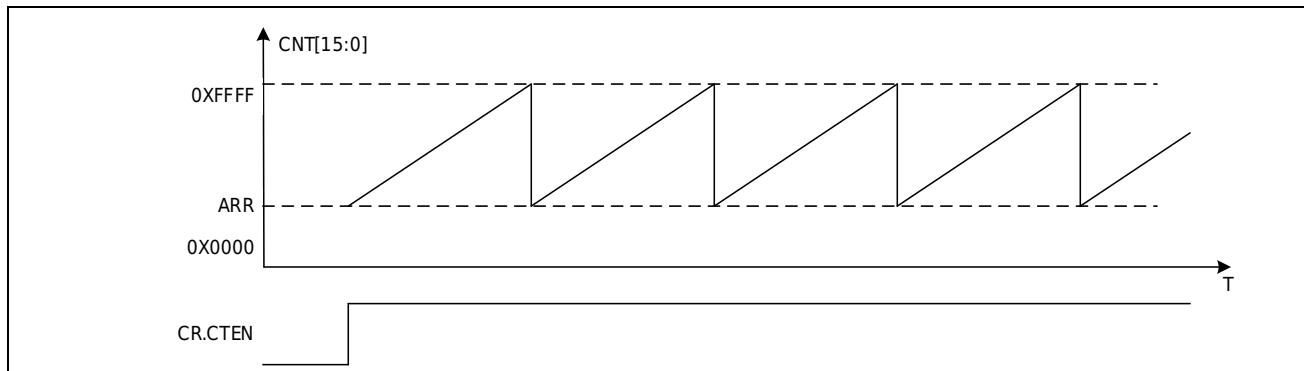

Figure 14-5 16-bit heavy load counting waveform

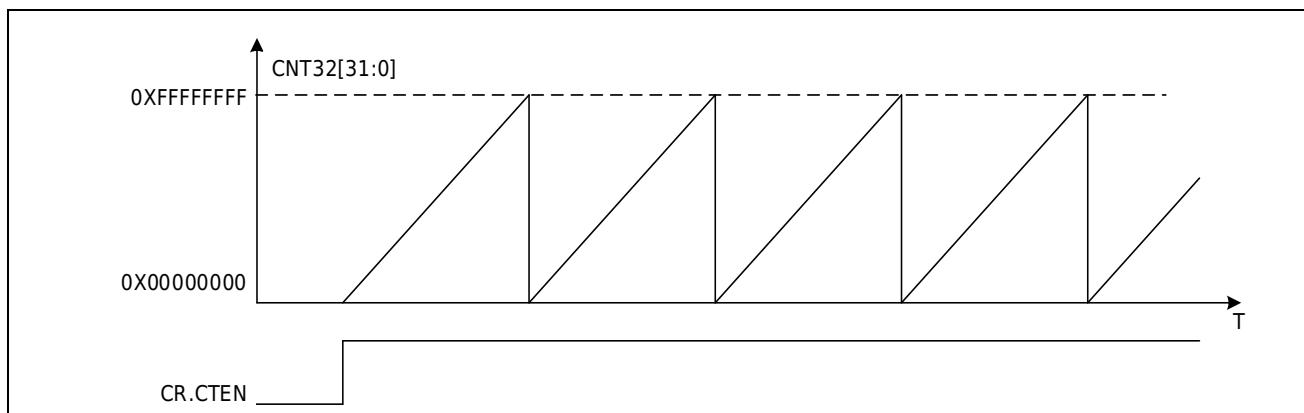

Figure 14-6 32-bit free-counting waveform

14.2.4.3 Counting function

Counting functions are used to determine the number of times an event occurs. In the count function, the counter increments every falling edge of the corresponding input clock. The input signal is sampled by the internal tclk, so the external input clock frequency cannot exceed the

system tclk clock. Counting to the maximum value will overflow and generate an interrupt. The interrupt flag needs to be cleared by software.

14.2.4.4 Timing function

The timing function is used to generate interval timing. In the timing function, the timer has a pre-divided frequency, and the timer accumulates once per clock of each pre-divided frequency. When counting to the maximum value, it will overflow and generate an interrupt. The interrupt flag needs to be cleared by software.

14.2.4.5 Timing diagram

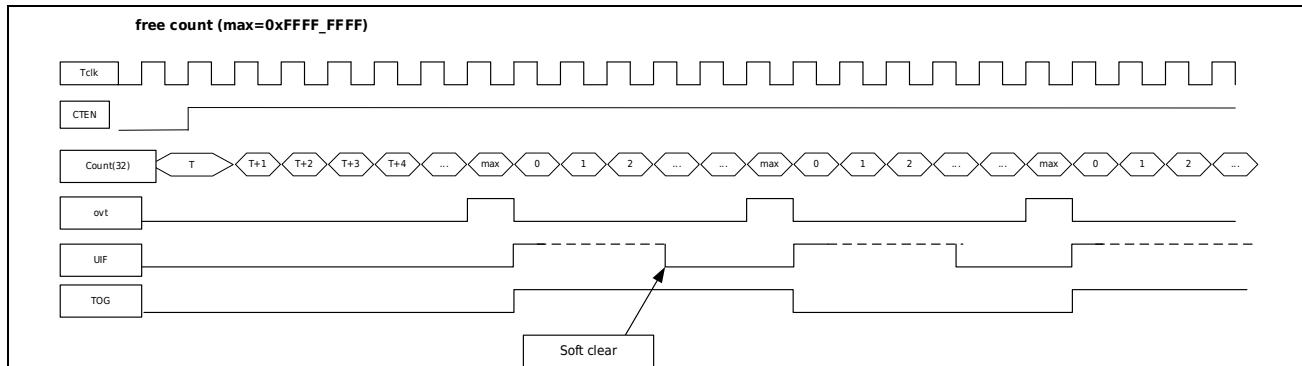

Figure 14-7 Free Count Timing Diagram

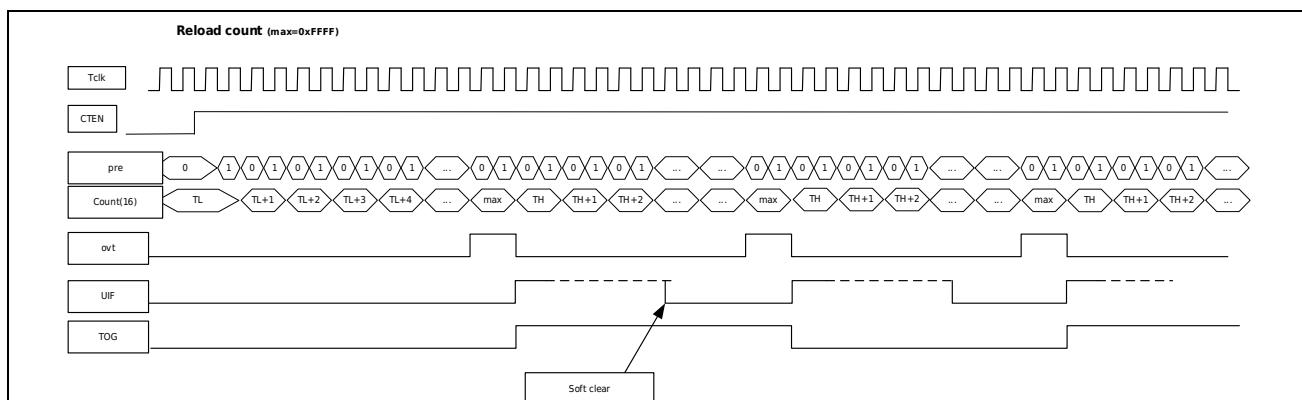

Figure 14-8 Timing diagram of heavy load counting (prescaler is set to 2)

14.2.4.6 Buzzer function

The Buzzer can be realized through the flipping output function of the timer. To use the toggle output requires enabling the DTR.MOE control bit. Setting CR.TOG_EN to 0 can set port CHA, CHB output to 0 at the same time. When the counting clock is 4M, the timer reload mode configuration of Buzzer outputting different frequencies is as follows:

Buzzer frequency	Counter period	Counter count value	Counter reload value	CNTL initial value	CNTH reload value
1000Hz	0.5ms	2000	63536	0XF830	0XF830
2000Hz	0.25ms	1000	64536	0XFC18	0XFC18
4000Hz	0.125ms	500	65036	0FE0C	0FE0C

14.2.4.7 Setup example

Reload Timer Settings

1. Set timer mode M0CR.MODE=0
2. Set load value ARR
3. Set the counter initial value CNT
4. Clear interrupt flag
5. Enable interrupt M0CR.UIE
6. Enable reload mode M0CR.MD
7. Start timer M0CR.CTEN

Gated external clock free count setting

1. Set timer mode M0CR.MODE=0
2. Set the counter initial value CNT
3. Enable gate function M0CR.GATE
4. Select gate active level M0CR.GATEP
5. Clear interrupt flag
6. Enable interrupt M0CR.UIE
7. Enable external clock mode M0CR.CT
8. Start timer M0CR.CTEN

BUZZER output control

1. Set the appropriate ARR value according to the output frequency
2. Set the timer to reload mode, refer to reload timer setting
3. Enable Output Enable DTR.MOE
4. Start another timer to control M0CR.TOGEN to realize frequency interval output.

14.2.5 Mode 1 pulse width measurement PWC

In this mode, the high level and low level or period width of the input pulse can be automatically measured.

The first valid edge counter is initialized to 0x0001, the second valid edge will stop counting, and the current count value will be stored in CMAR, and a capture interrupt CAF will be generated. If the counter overflows, an overflow flag will be generated. Setting overflow interrupt enable will generate overflow interrupt.

M1CR.edg1st	0	0	1	1
M1CR.edg2nd	0	1	0	1
Pulse width measurement	Upper edge ~ Upper edge Cycle width	Upper edge ~ lower edge High level width	Lower edge ~ upper edge Low level width	Lower edge ~ lower edge Cycle width

During period measurement, a period is measured at intervals of one period.

14.2.5.3 PWC one-shot mode

Set M1CR.ONESHOT=1 to set PWC single measurement, and CTEN will be cleared after the measurement is completed.

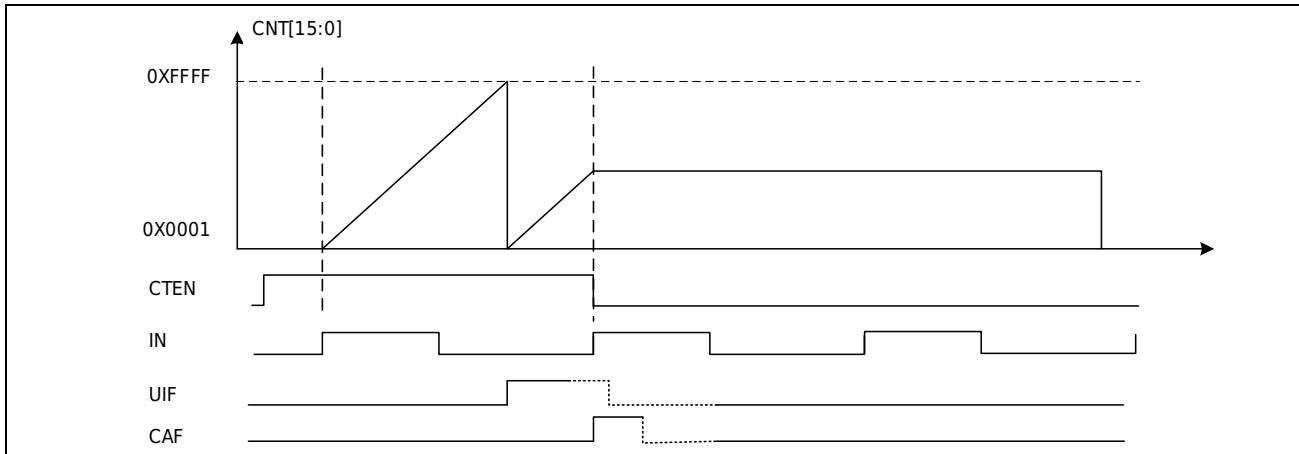

Figure 14-13 Rising edge-to-rising edge period measurement one-shot mode

14.2.5.4 Setup example

Pulse Low Level Measurement Setup

1. Set to pulse measurement mode M1CR.MODE=1
2. Set MSCR.TS to select the signal to measure
3. Set M1CR.edg2dn=0, M1CR.edg1st=1 to choose to measure low level
4. Clear interrupt flag
5. Enable overflow interrupt M1CR.UIE
6. Enable measurement end interrupt CR0.CIEA
7. Enable timer M1CR.CTEN
8. Read CCROA and the number of overflows in the interrupt service routine and clear the interrupt flag
9. Waiting for next measurement

Pulse high level single measurement setup

1. Set to pulse measurement mode M1CR.MODE=1
2. Set MSCR.TS to select the signal to measure
3. Set pulse single measurement mode M1CR.ONESHOT=1
4. Set M1CR.edg2dn=1, M1CR.edg1st=0 to choose to measure low level

5. Clear interrupt flag
6. Enable overflow interrupt M1CR.UIE
7. Enable measurement end interrupt CR0.CIEA
8. Enable timer M1CR.CTEN
9. Read CCR0A and the number of overflows in the interrupt service routine and clear the interrupt flag
10. End of measurement

14.2.6 Mode 2/3 compare capture mode

14.2.6.1 Counter

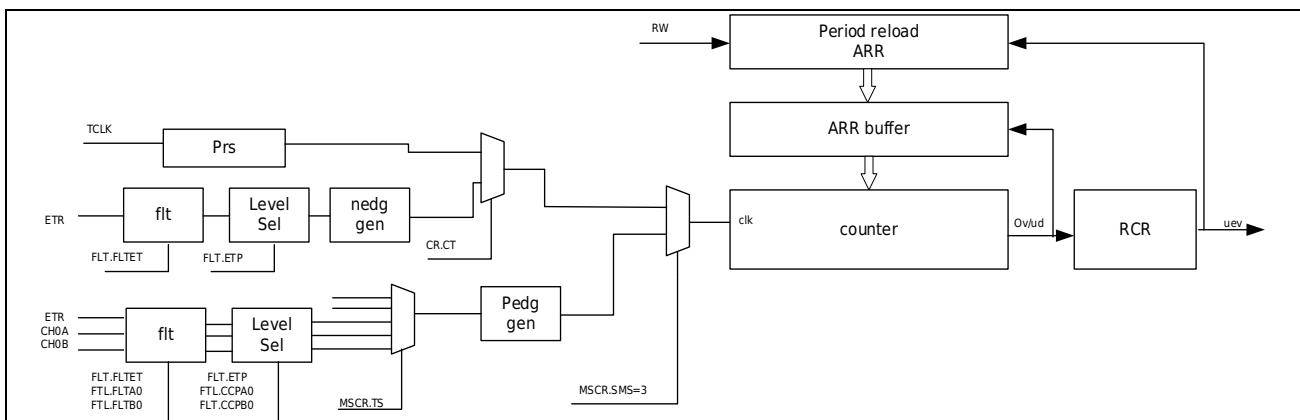

Figure 14-14 Counter Block Diagram

The main part of the counter is a 16-bit counter with associated autoload registers. This counter can count up (mode 2), count down (mode 2) or count up and down in both directions (mode 3). The clock of the counter can be divided by the prescaler PRS, or ETR can be selected to input an external clock or the external input signal and internal interconnection signal selected by MSCR.TS.

- Counter basic units include:
- Counter Register CNT
- Prescaler register CR.PRS
- Autoload Register ARR
- Repeat count register RCR
- Clock selection control registers FLT, CR0, MSCR, CR

The autoload register has a cache function, and the reload value is updated from the cache register to the counter after the counter generates an event update. When the counter is stopped or the cache function is disabled, the autoload register is immediately updated to the cache register. When the timer is running and the parallel cache function is valid, the value written to the autoload register will not be updated to the cache register immediately, and the autoload register will be updated to the cache register only after the event is updated.

Clock selection and gating function, trigger function, reset function refer to the chapter of mode 2/3 slave mode.

14.2.6.2 counter waveform

Mode 2 is a sawtooth counting waveform, and the counting direction can be changed by setting CR.DIR.

CR.DIR is set to 0, the counter is in up-counting mode. In this mode, the counter counts from 0 to the auto-reload value (TIMx_ARR), and then restarts Counts from 0 and generates a counter overflow event. (UEV) is generated when the number of repetitions counted up reaches the number programmed in the repeat counter register plus one (TIMx_RCR+1). Otherwise, an update event will be generated every time the counter overflows.

An update event is also generated when the UG bit of the TIMx_CR register is set (by software or using a slave mode controller).

When an update event occurs, all registers are updated and the update flag (UIF bit in the TIMx_IFR register) is set (depending on the URS bit):

- The auto-reload cache value will be updated with the ARR register value
- The compare buffer value will be updated with the compare register CCRxy

The figure below shows the counter waveforms of different counting directions when ARR=0X2C

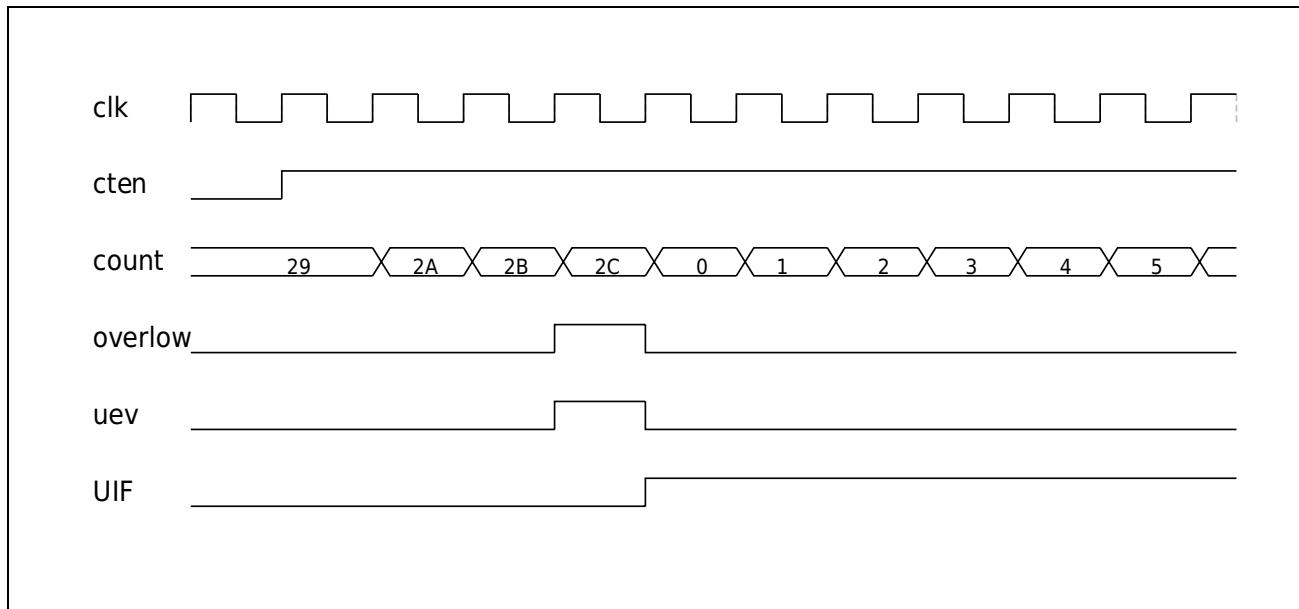

Figure 14-15 Count Up Without Prescaler

The number of counting overflow cycle clocks is ARR+1,

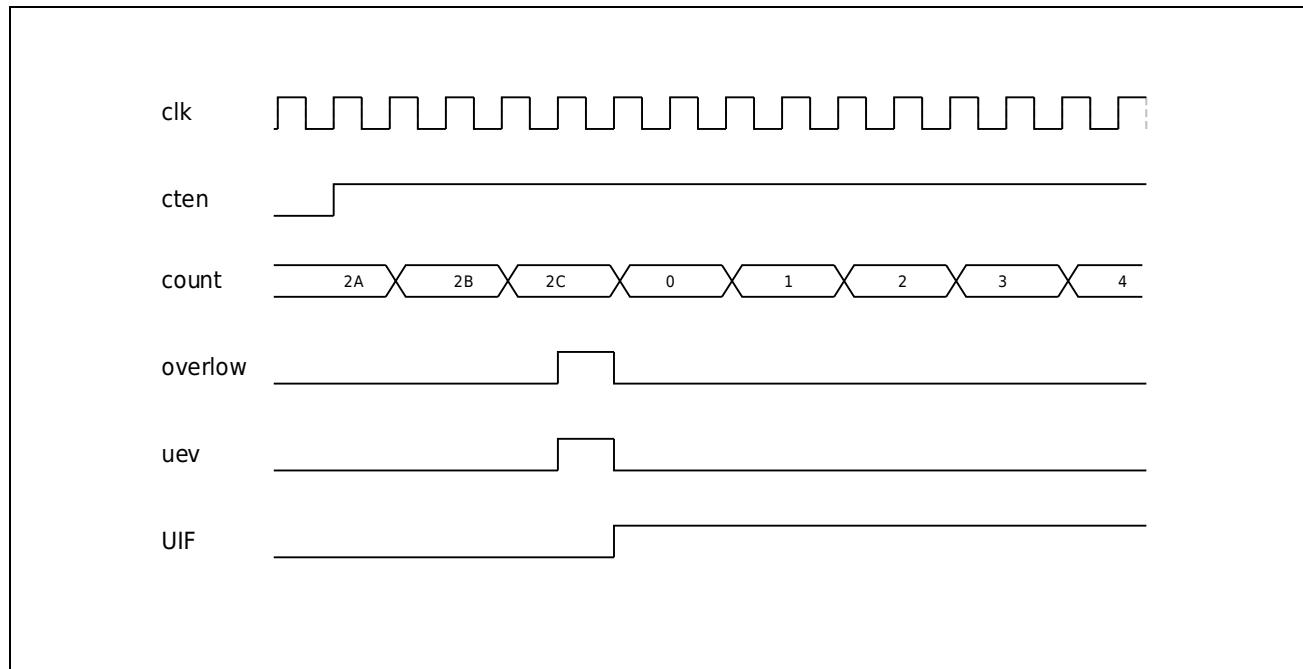

Figure 14-16 Up Counting with Prescaler

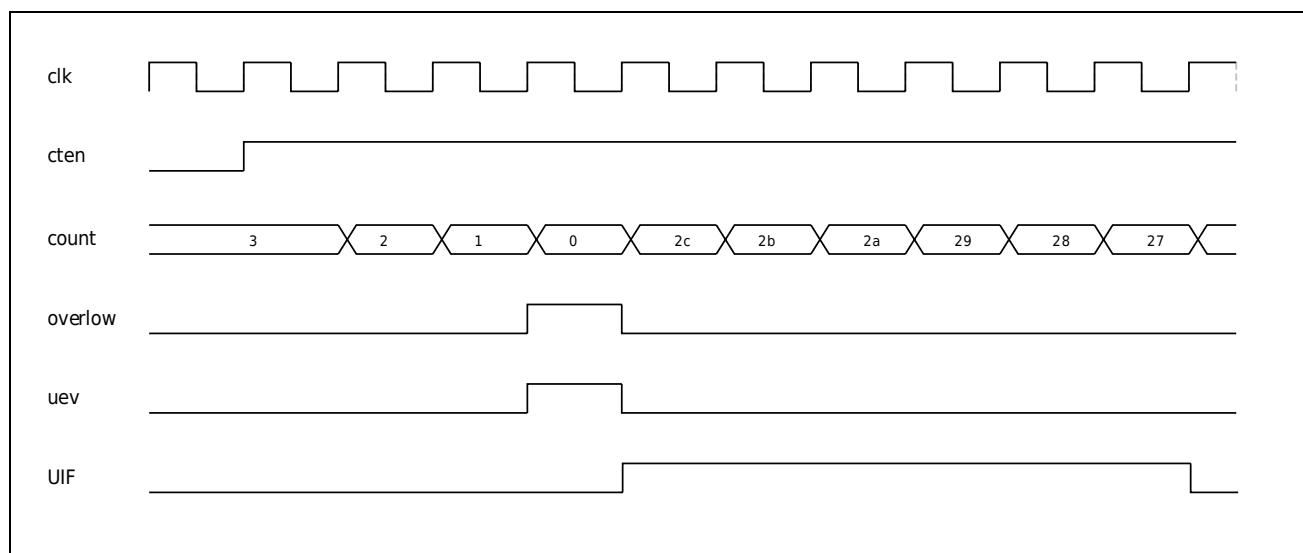

Figure 14-17 Down counting without prescaler

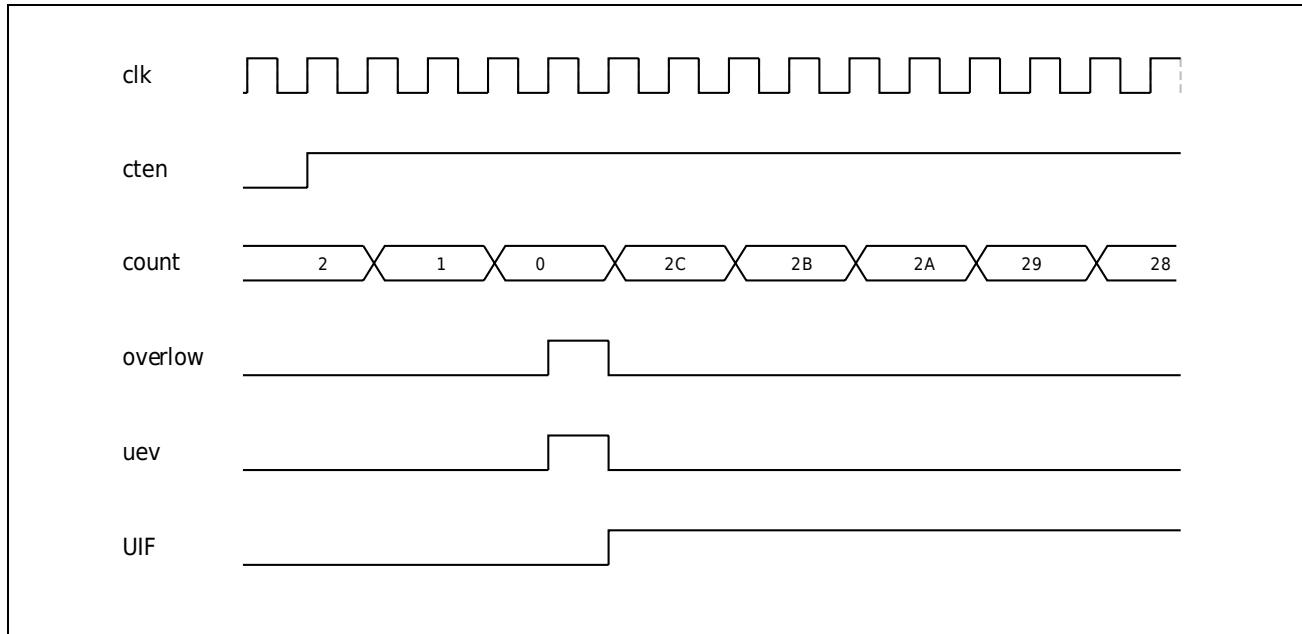

Figure 14-18 Down counting with prescaler

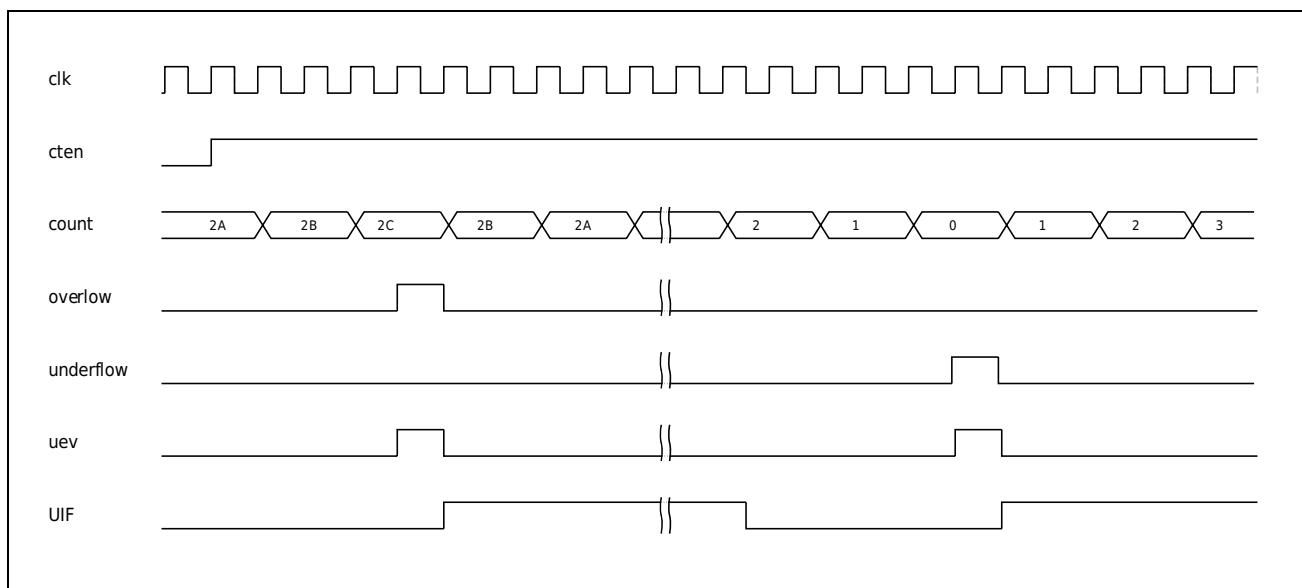

Figure 14-19 Up and down counting with prescaler

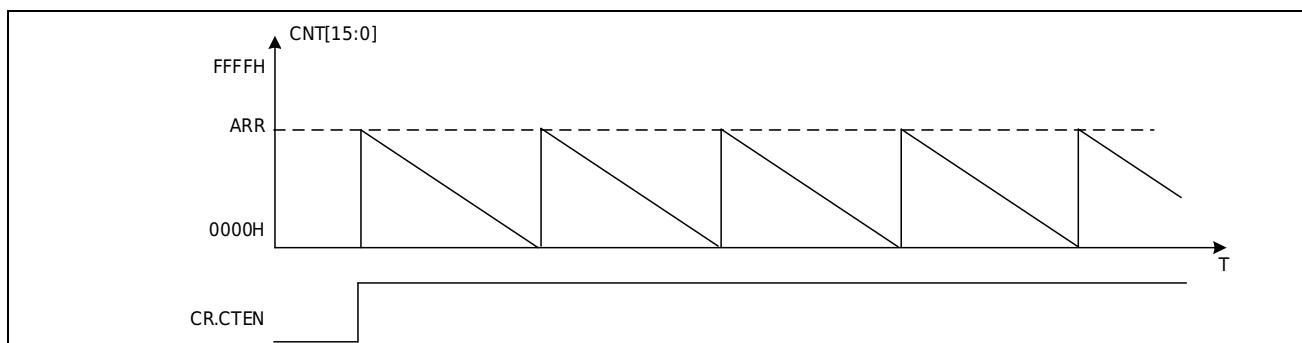

Figure 14-20 Edge-Aligned Timer Waveform (DIR = 1)

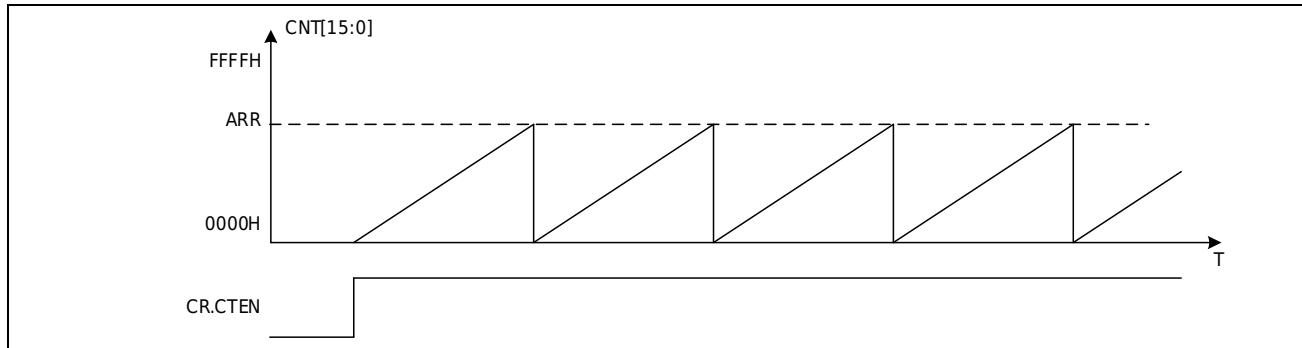

Figure 14-21 Edge-Aligned Timer Waveform (DIR = 0)

Mode 3 is a triangular wave counting waveform, the counting direction control bit is read-only, and the counting direction cannot be changed.

The CR.DIR direction bit is read-only in center-aligned (triangular wave) mode. Write value is invalid. Switching from other modes to center-aligned mode DIR is automatically cleared to 0. DIR is automatically cleared in reset mode by software event update and external trigger in slave mode.

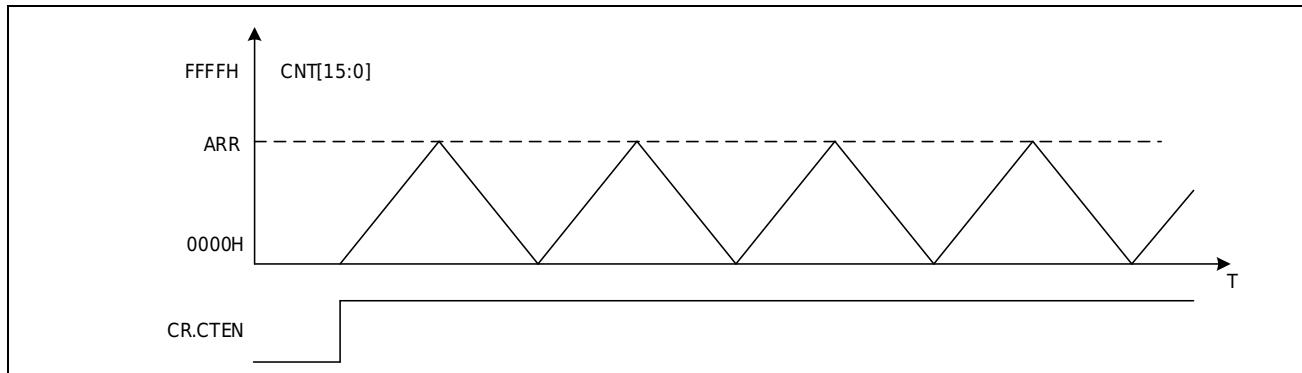

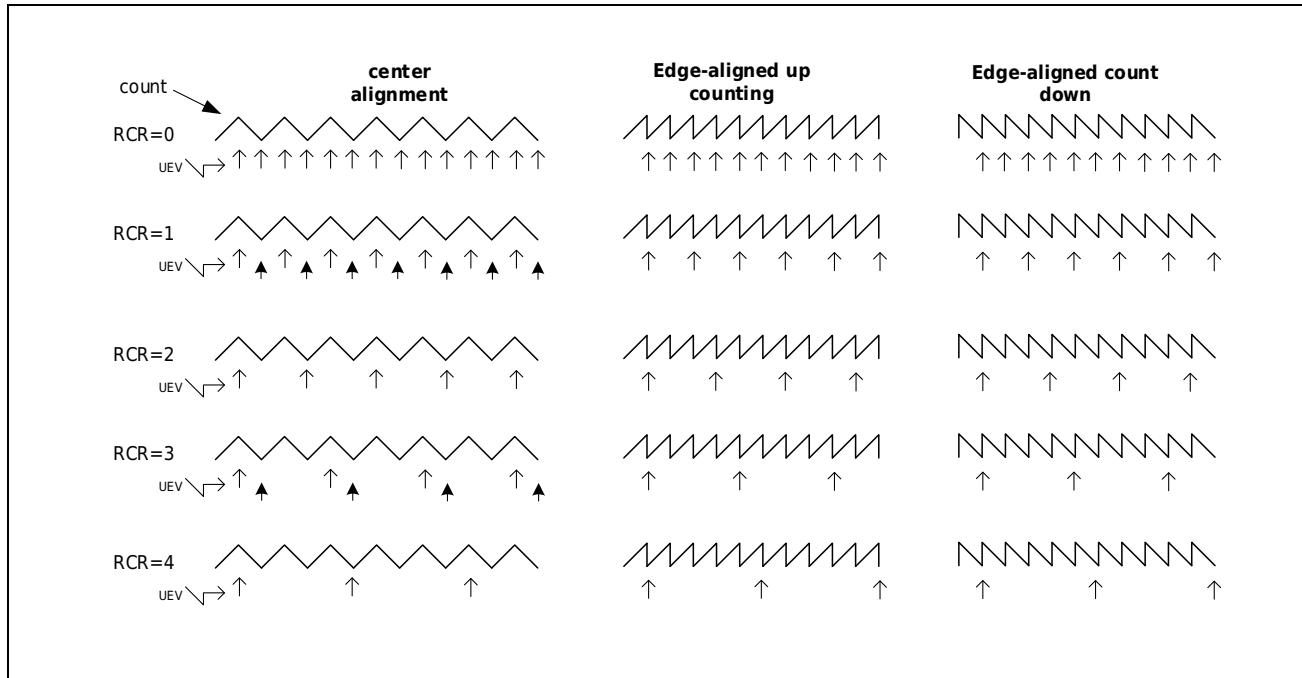

Figure 14-22 Center Aligned Counter Waveform

14.2.6.3 Repeat count

A repeating counter uses the counter's overflow to count down. counting to 0, that is, when the counter overflows once the value set by the repeat register is added. When the cache register is enabled, the cycle reload register is updated to the cycle cache register. In compare mode, the value of the compare register is updated to the compare cache register.

The repeat counter is decremented when the following conditions are true

- Each time the counter overflows in up counting mode
- Each time the counter underflows in down counting mode
- Every overflow and every underflow in triangle wave mode

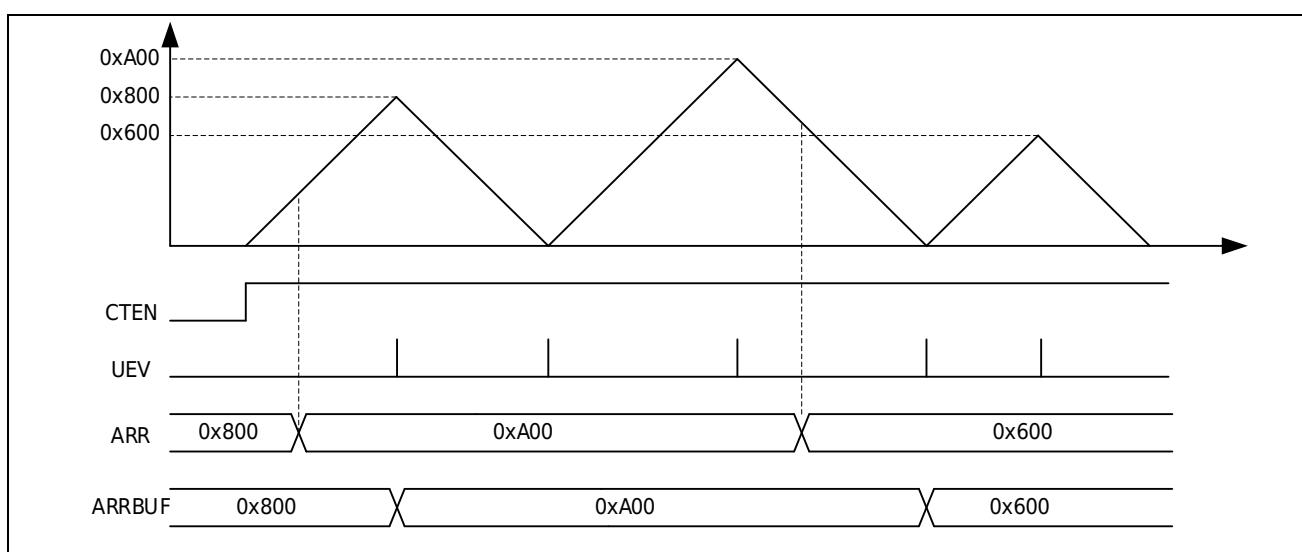

**Figure 14-23** Repeat counter generates update timing

In addition to generating events to update UEV through repeated counters on overflow and underflow, you can also generate software and slave mode reset events to update UEV by writing register CR.UG; at this time, you need to configure CR.URS.

14.2.6.4 data cache

The auto-reload data ARR and the comparison register can be configured with a cache function. When the cache function is valid, the written period value ARR and comparison value CCR will only take effect when the UEV event is updated.

The update timing diagram of the auto-reload value in different counting modes is as follows:

**Figure 14-24** Buffer enable in triangle wave mode

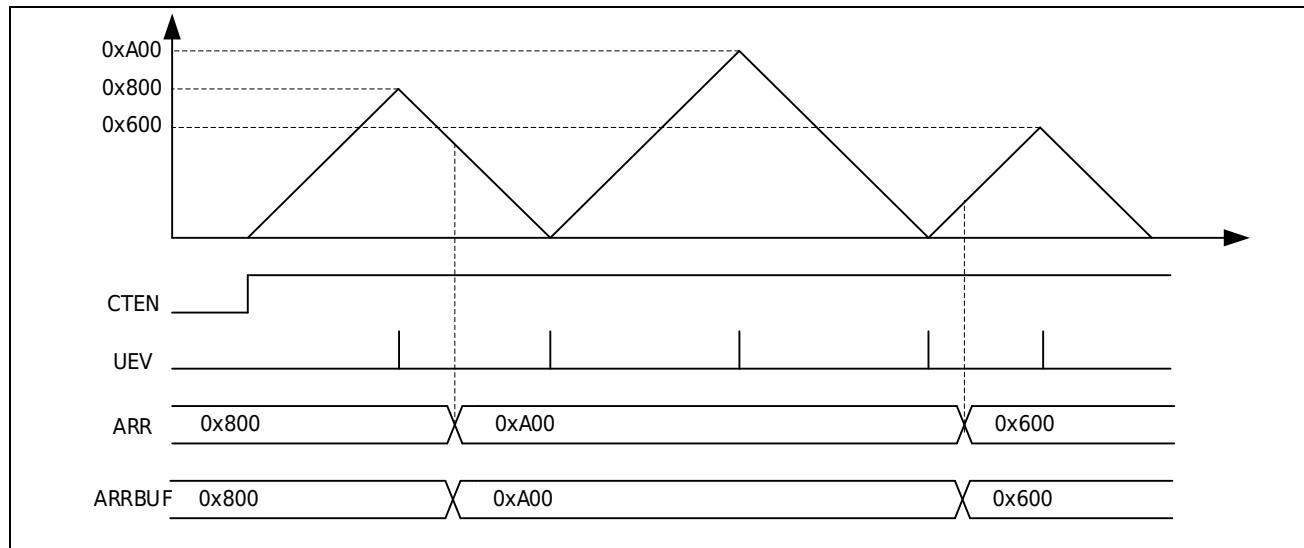

Figure 14-25 Buffer invalidation in triangle wave mode

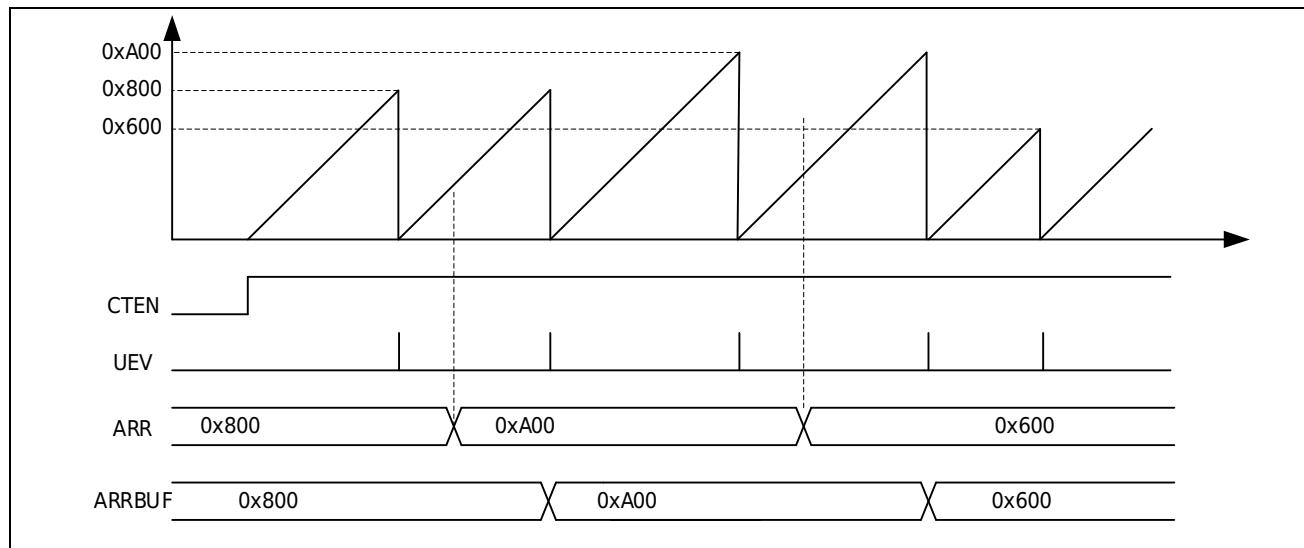

Figure 14-26 Up count buffer enable in sawtooth mode

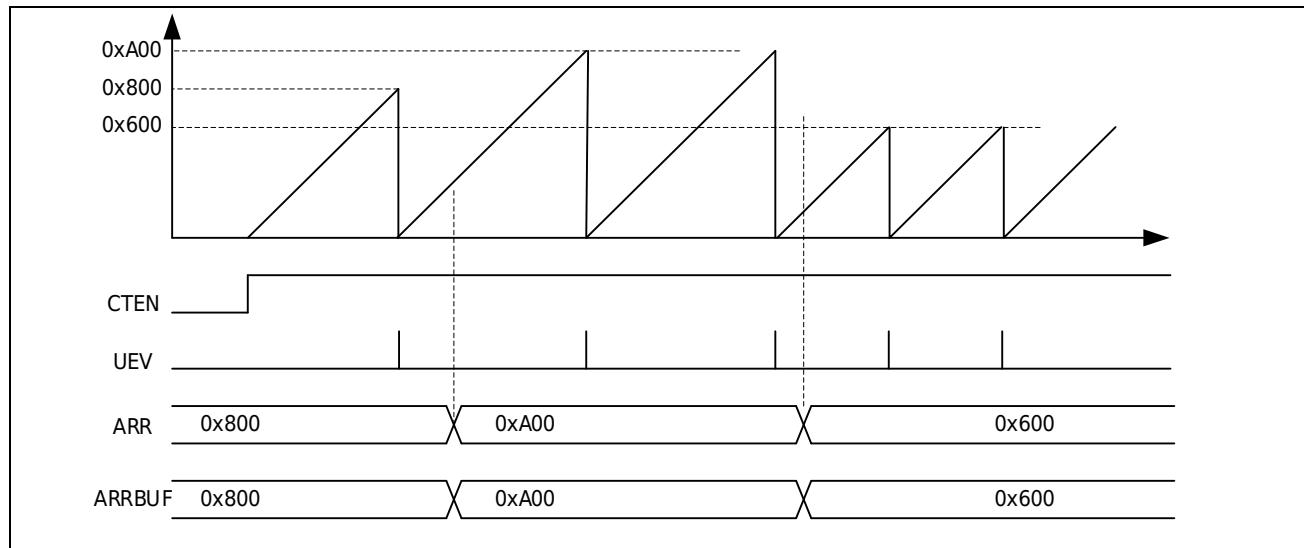

Figure 14-27 The up count buffer is invalid in sawtooth mode

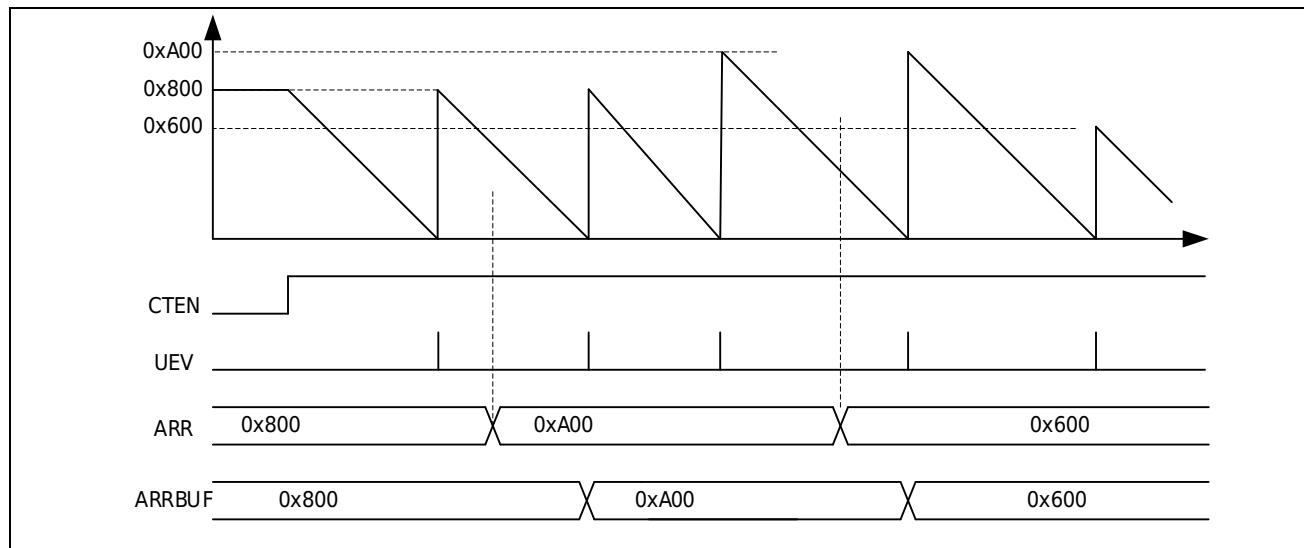

Figure 14-28 Count buffer enable in sawtooth mode

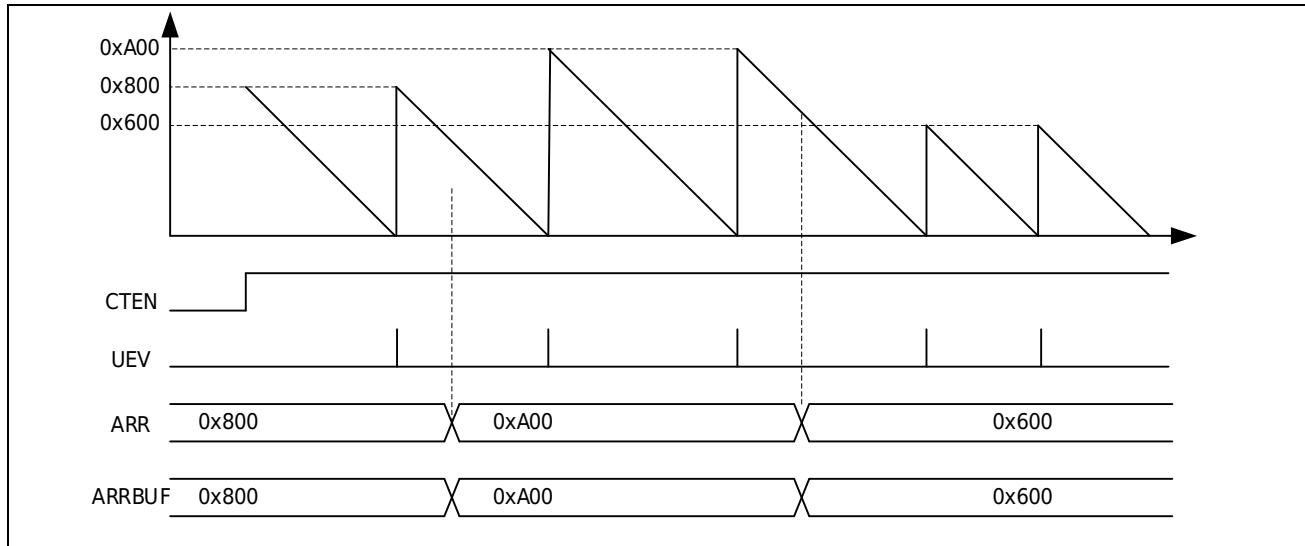

Figure 14-29 The counter buffer is invalid in sawtooth mode

In triangular wave mode and sawtooth counting mode, if the cache is not enabled, when changing ARR, the current counter value should be smaller than the ARR cycle value to be changed, otherwise the current cycle will count to 0xFFFF.

The update status of the comparison cache is consistent with that of the periodic cache, and the sequence diagrams are not listed here.

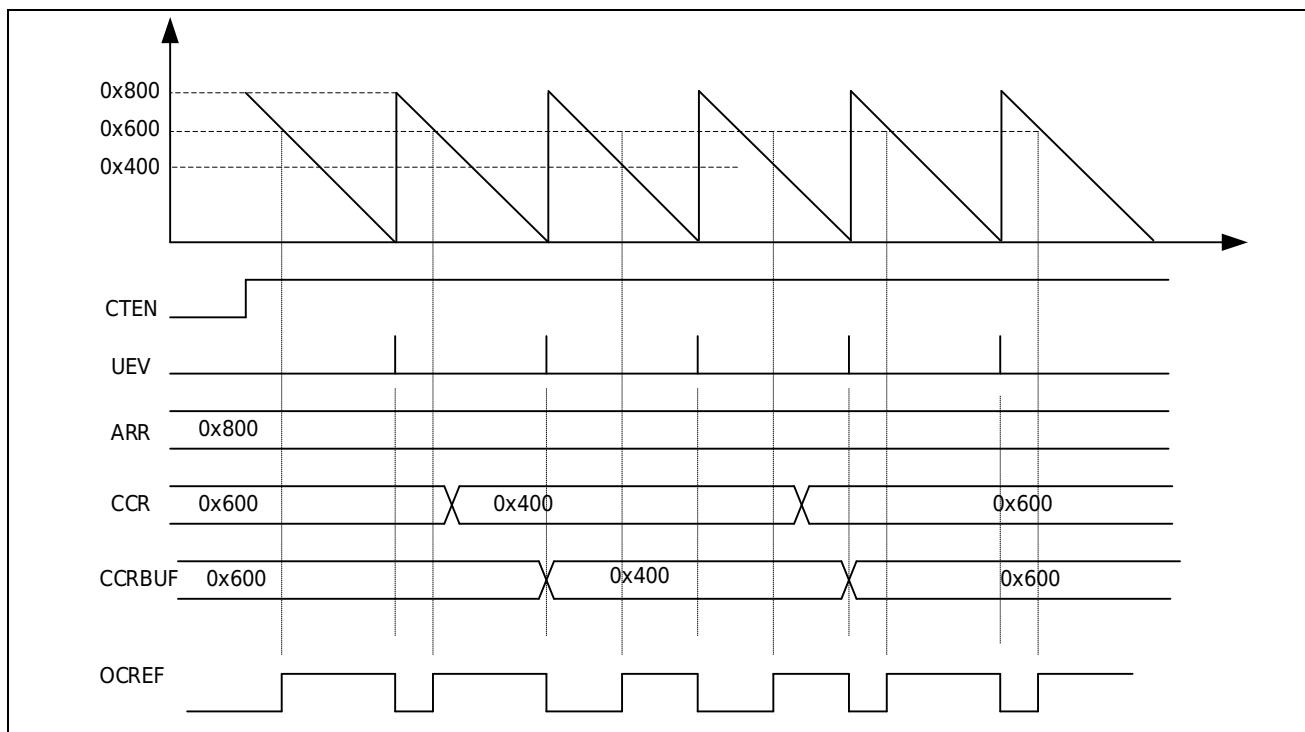

Figure 14-30 Count compare buffer enable in sawtooth mode

14.2.6.5 Compare output OCREF

The comparison output OCREFA can be configured as a single-point comparison, and the comparison register CCRA is used to control the output of OCREFA; the comparison output of OCREFA can also be configured as a two-point comparison, and the comparison registers CCRA and CCRB are used to control the comparison output of OCREFA.

OCREFB can only use single-point comparison, and the comparison register CCRB is used to control the comparison output of OCREFB.

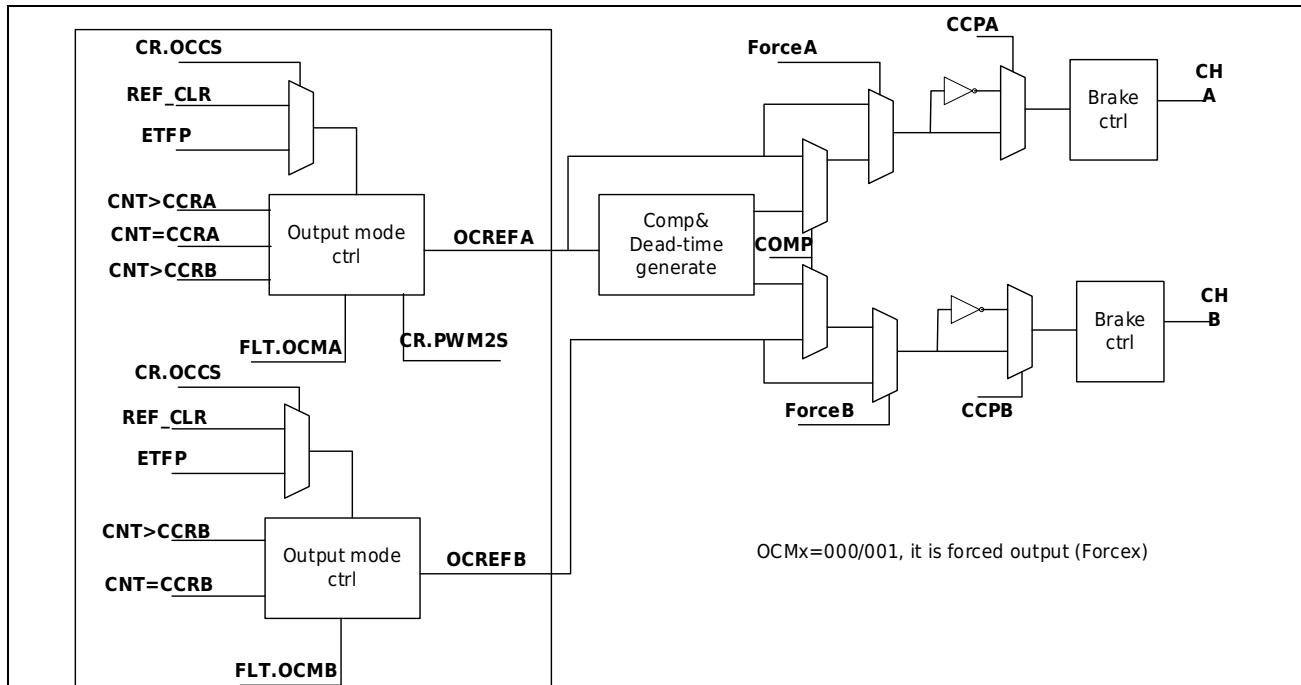

Figure 14-31 OCREF output block diagram

OCREF output is selected using OCMx

000: forced to 0

001: Forced to 1

010: Forced to 0 when comparing matches

011: Forced to 1 when comparing matches

100: flip when comparison matches

101: Output a high level for one count period when comparing matches

110: PWM mode 1

Single point comparison:

When counting up, CNT<CCRxy outputs high, and when counting down, CNT>CCRxy outputs low level

Two-point comparison:

- 1) Counting CCRxA < CNT ≤ CCRxB output on the sawtooth wave is low level
- 2) Counting under sawtooth wave CCRxA < CNT ≤ CCRxB output is high level
- 3) Triangular wave up counting CNT < CCRxA output high, down counting CNT > CCRxB is low level

111: PWM mode 2

Single point comparison:

When counting up, CNT < CCRxy outputs low, when counting down, CNT > CCRxy outputs high level

Two-point comparison:

- 1) Counting CCRxA ≤ CNT < CCRxB output on the sawtooth wave is high level
- 2) Counting under sawtooth wave CCRxA ≤ CNT < CCRxB output is low level
- 3) Triangular wave up count CNT < CCRxA output low, down count CNT > CCRxB is high level

Note: Forced output has high priority, when forced output is valid, complementary output control is invalid.

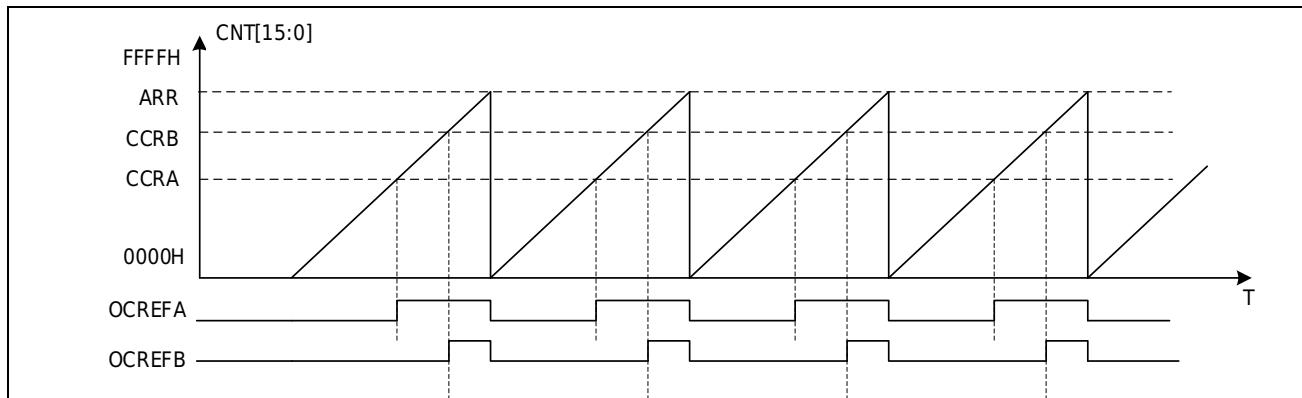

Figure 14-32 Sawtooth counting single point comparison OCREF output waveform(OCMx=111)

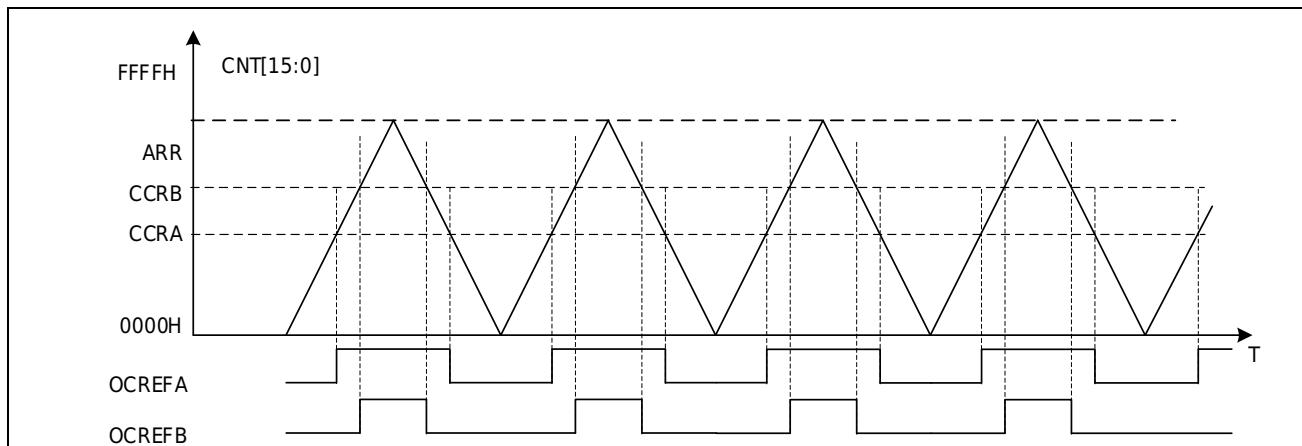

Figure 14-33 Triangular wave counting single point comparison OCREF output waveform (OCMx=111)

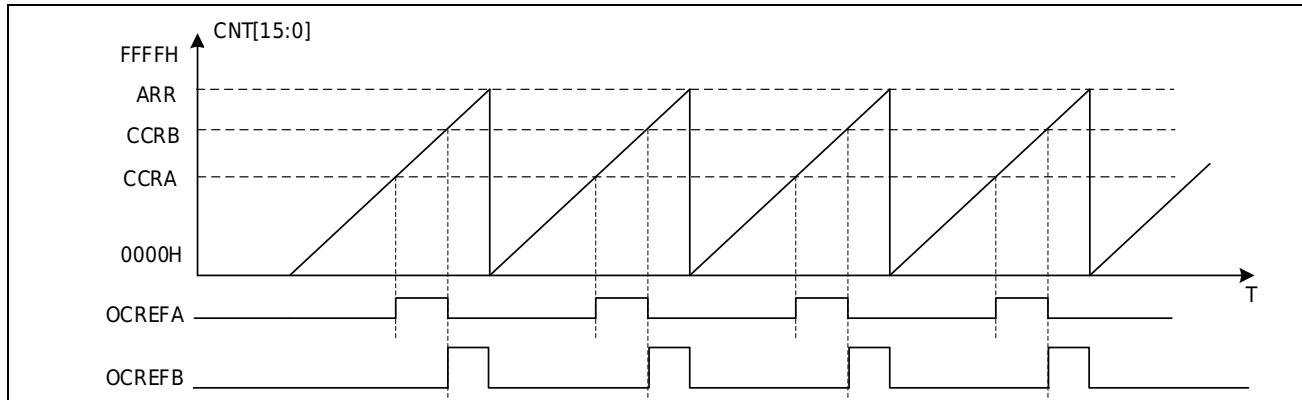

Figure 14-34 Sawtooth wave counting double-point comparison OCREF output (OCMx=111)

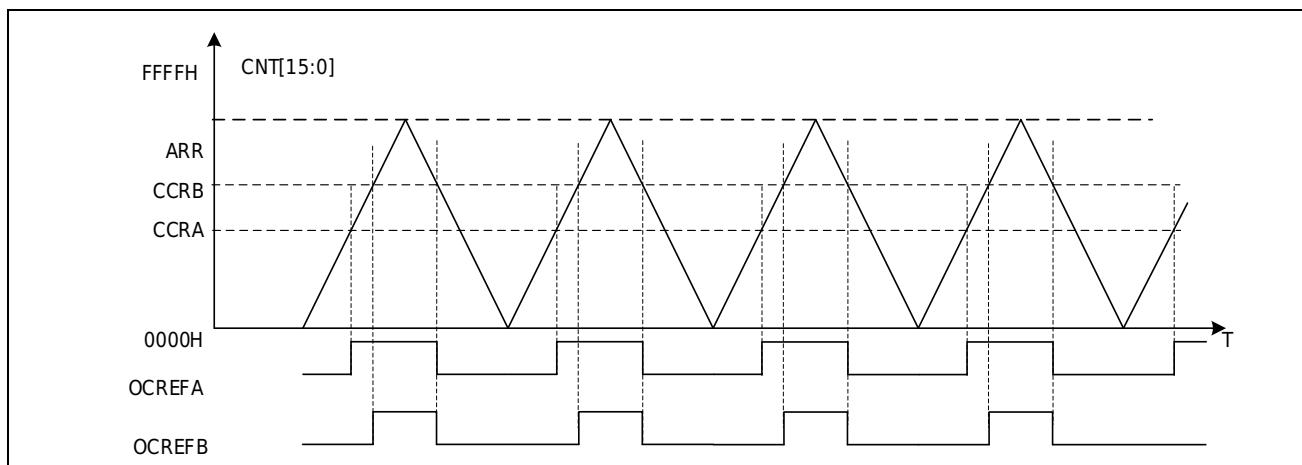

Figure 14-35 Triangular wave counting double-point comparison OCREF output (OCMx=111)

14.2.6.6 Independent PWM output

CHA is controlled by OCREFA, and the output of CHB is controlled by OCREFB. Through CRCHx.CCPA, CRCHx.CCPB can control the reverse of CHA and CHB output.

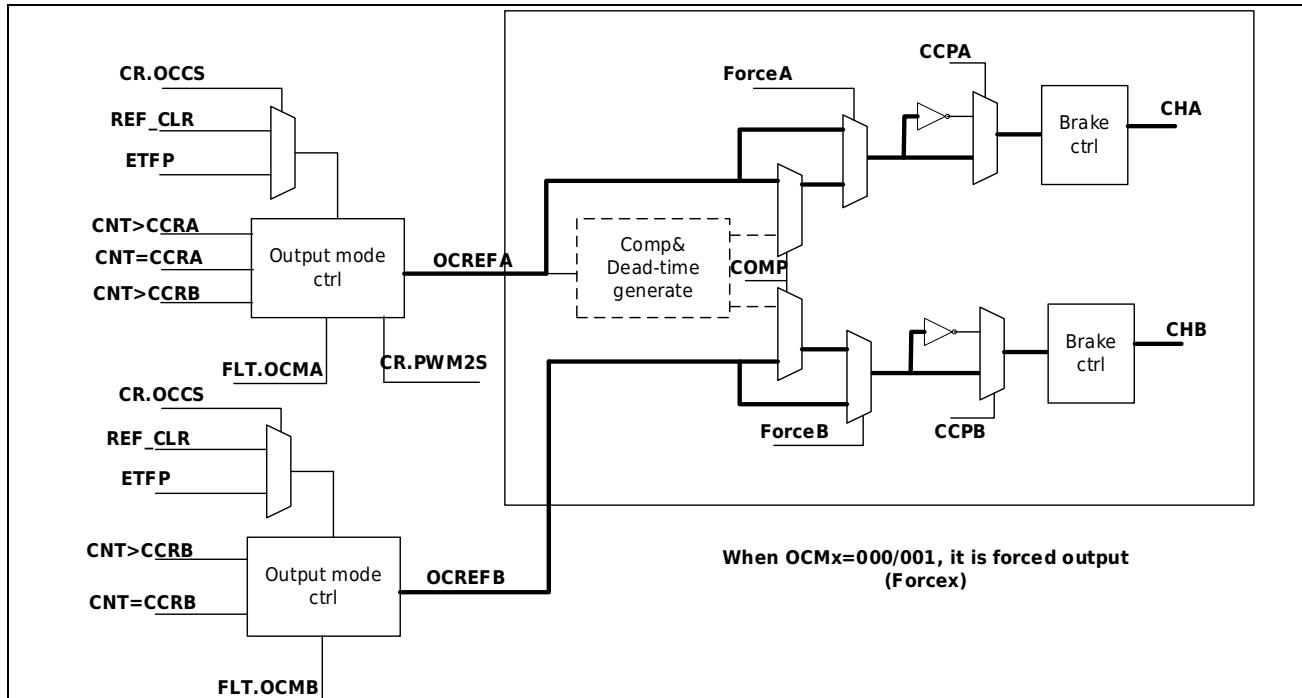

Figure 14-36 Independent PWM Output Block Diagram

Relationship between PWM output and OCREF

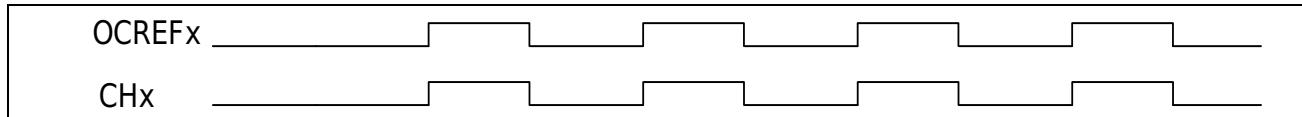

Figure 14-37 PWM output waveform when CCPx=0

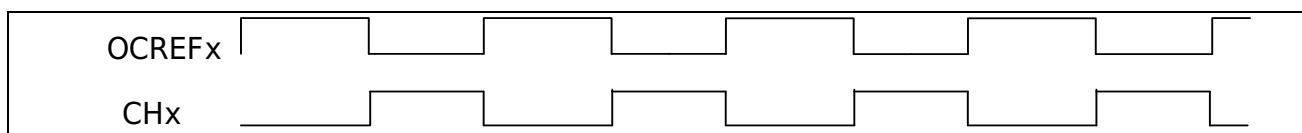

Figure 14-38 PWM output waveform when CCPx=1

14.2.6.7 Complementary PWM output

CHA is controlled by OCREFA, and OCREFB controls the output of CHB at the same time. The compare register CCRxB can be used as a dedicated compare control ADC trigger.

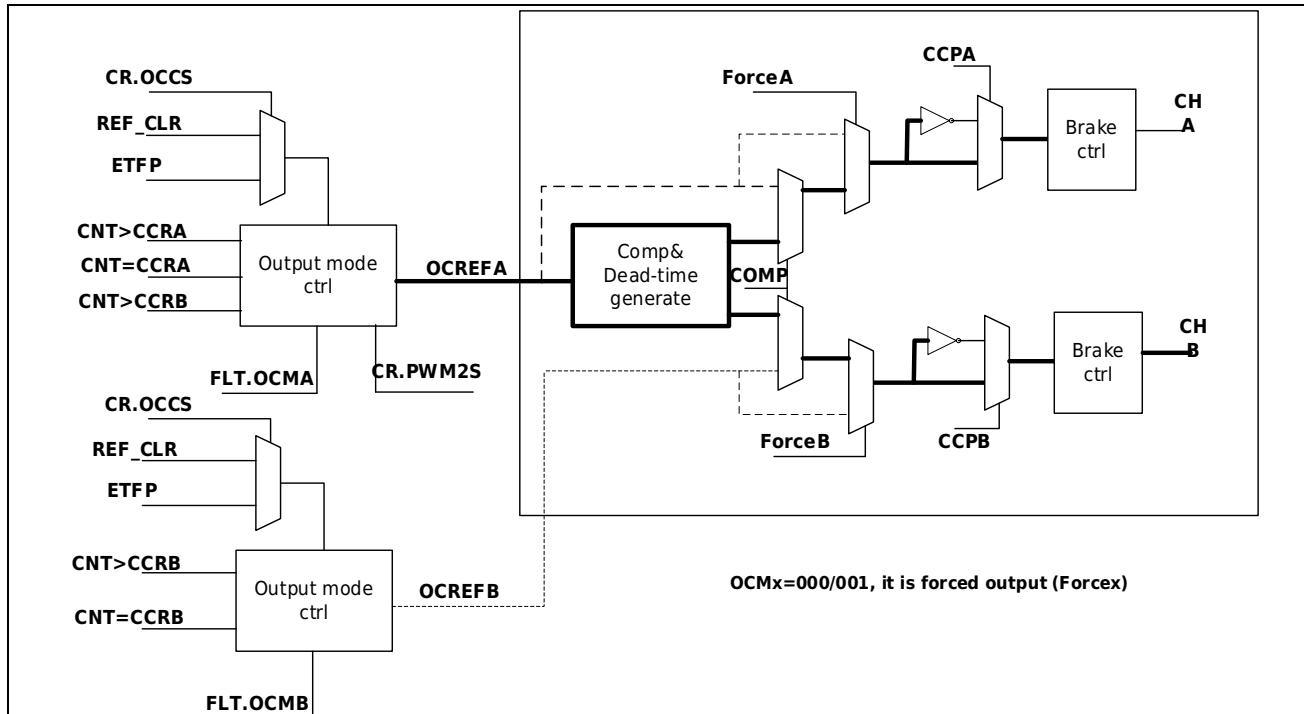

Figure 14-39 Complementary PWM Output Block Diagram

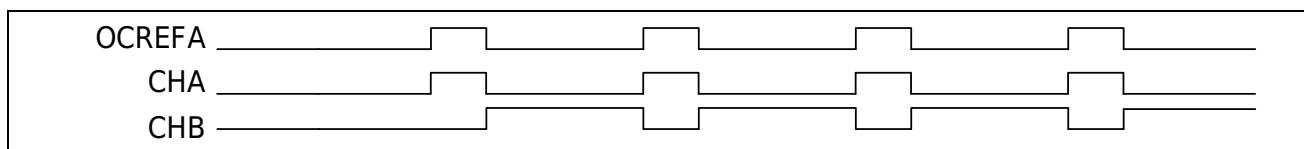

Figure 14-40 Complementary PWM output waveform

14.2.6.8 PWM output with dead zone

The dead-time function can be set in complementary PWM output mode.

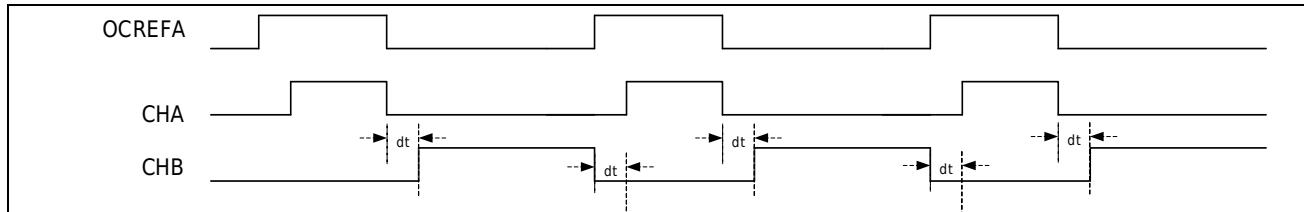

Figure 14-41 Complementary PWM output waveform

The dead time is controlled by 8-bit DTR, and the relationship between the dead time dt and DTR is as follows

DTR[7] = 0	T = DTR[6:0] + 2	2-129	step=1
DTR[7:6] = 10	T = {DTR[5:0] + 64} * 2 + 2	130-256	step=2
DTR[7:5] = 110	T = {DTR[4:0] + 32} * 8 + 2	258-506	step=8
DTR[7:5] = 111	T = {DTR[4:0] + 32} * 16 + 2	514-1010	step=16

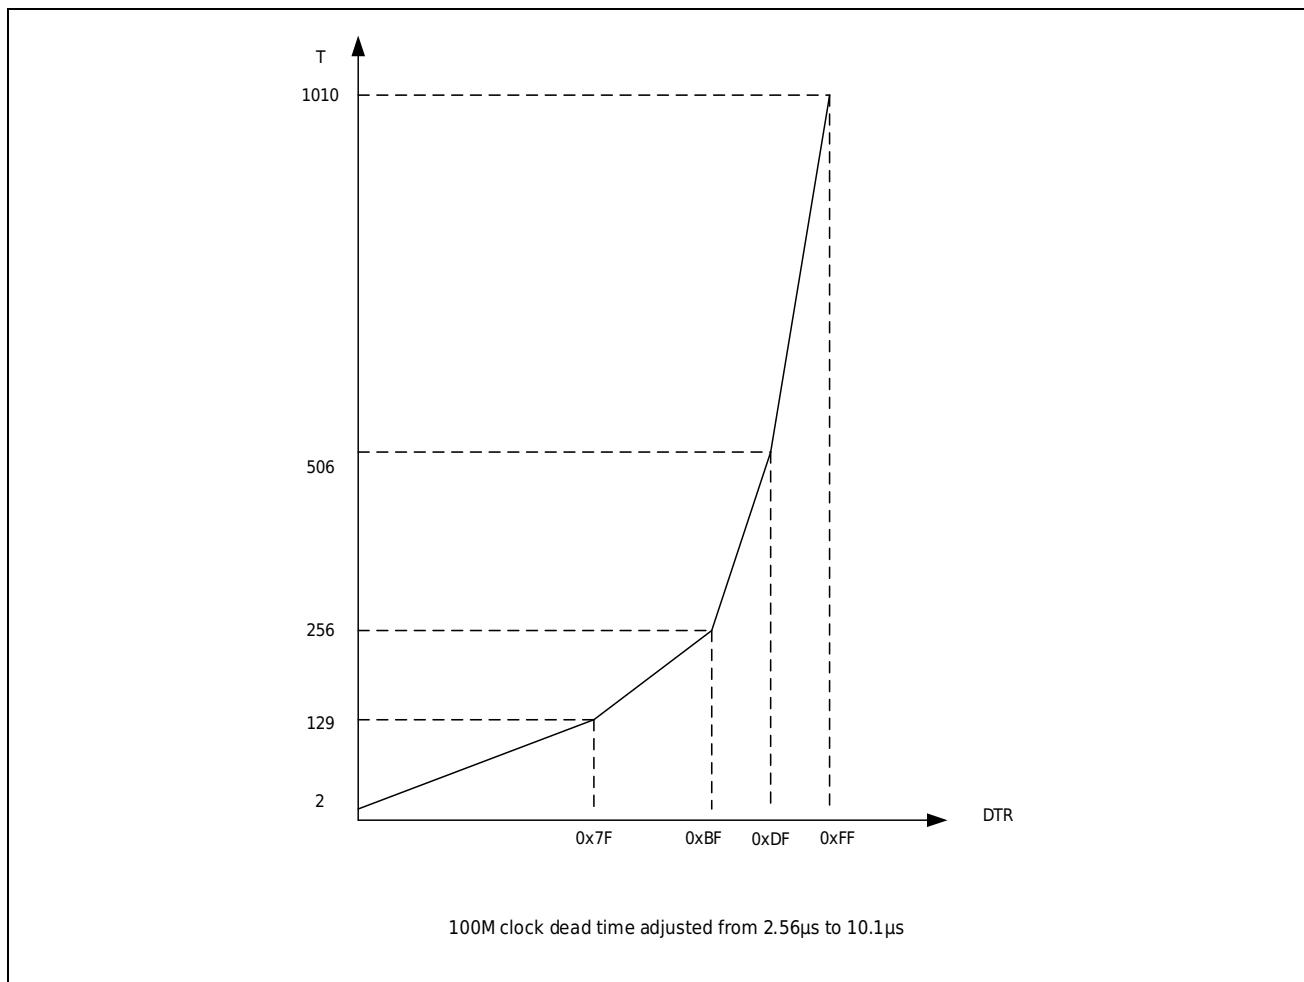

Figure 14-42 Dead time

14.2.6.9 Single pulse output

Single pulse mode (ONE SHOT) is a special case of the above PWM mode. In this mode, the counter can be triggered by an excitation signal to start, and can generate a programmable pulse width pulse after a programmable delay.

The counter can be started by the slave mode controller, can be generated in output compare mode or PWM mode. Will

ONESHOT bit in the TIMx_M23CR register to 1. In this way, the counter will automatically stop when the next update event UEV occurs.

Do not set the initial value of the counter in the sawtooth counting mode to 0 in the single pulse mode, and do not set the counting value in the up counting mode to be greater than or equal to ARR.

The output pulses are only generated correctly when the comparison value differs from the counter initial value. Before starting (when the timer is waiting to be triggered), the following configurations must be made:

- When counting up: CNT<CCRxy \leq ARR (special attention, 0<CCRxy),
- When counting down: CNT>CCRxy.

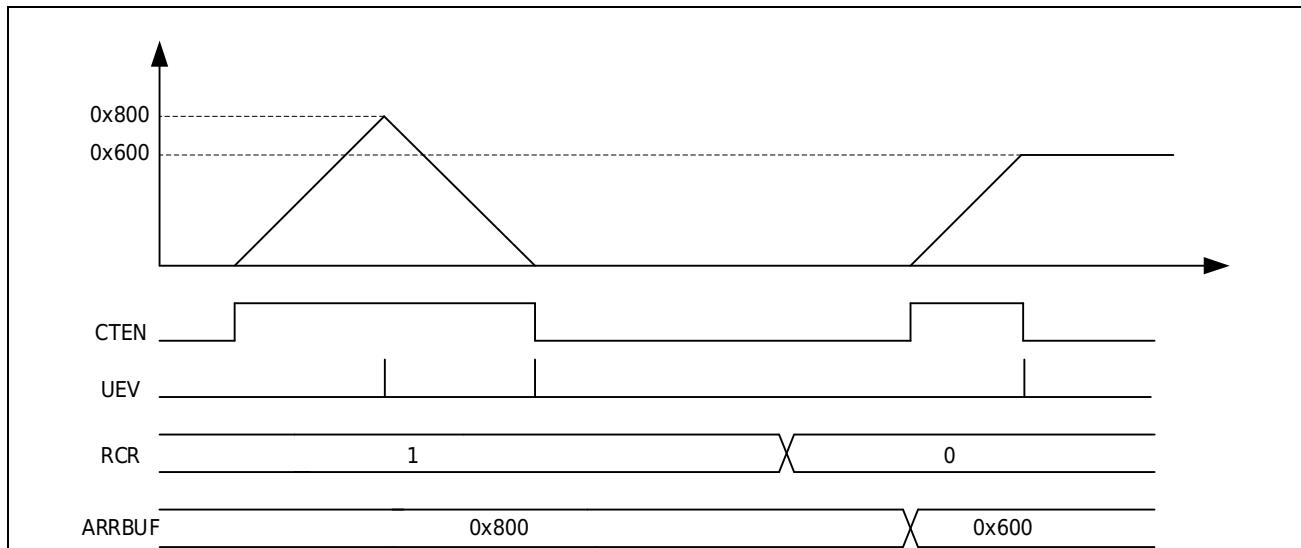

Figure 14-43 Single pulse counting in triangle wave mode

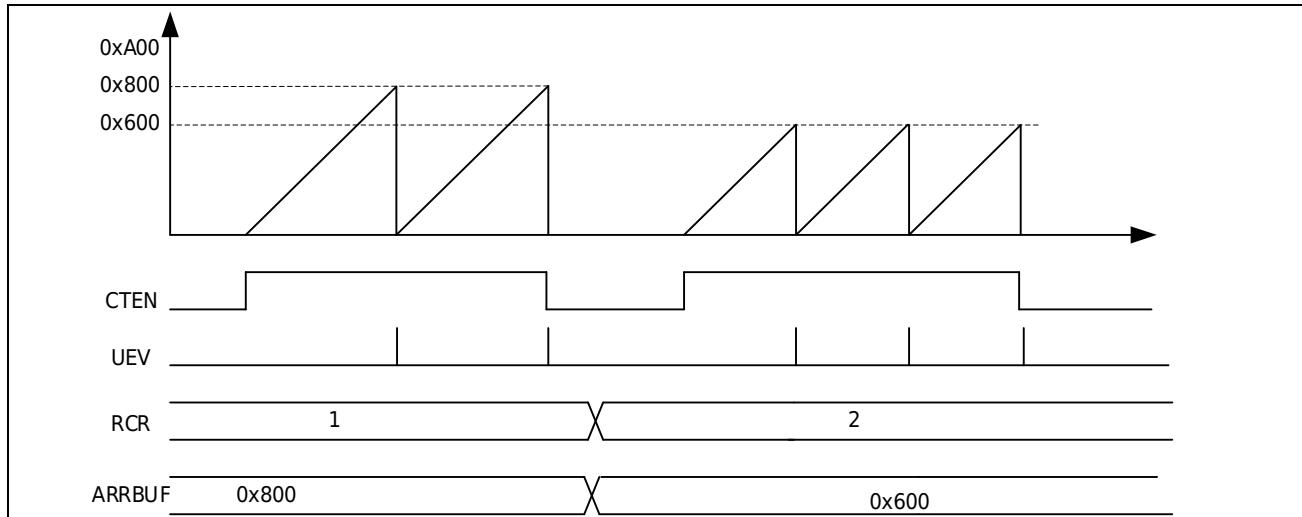

Figure 14-44 Counting Single Pulse Mode on Ramp Waveform

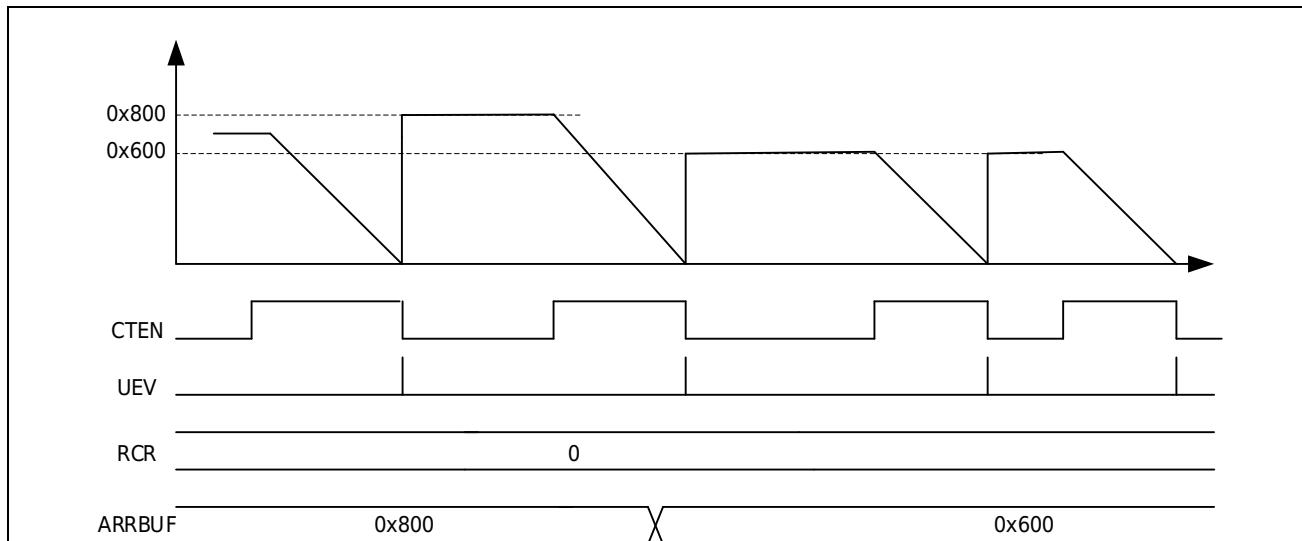

Figure 14-45 Counting single pulse mode under sawtooth waveform

14.2.6.10 compare interrupt

The sawtooth comparison match will set the corresponding flag of the IFR register to 1, and if the interrupt is enabled CRCH_x.CIE_y ($x=0,1,2; y=A,B$) will trigger an interrupt.

For triangular wave comparison match, you can select up-count comparison match, down-count comparison match or both comparison matches separately.

Compare A Compare Match When the count value is equal to CCR_xA, use CR.CIS control uniformly.

When CR.CIS=2'b00 compare match no output

When CR.CIS=2'b01 compare match when counting up

When CR.CIS=2'b10 compare match when counting down

When CR.CIS=2'b11 Comparing matches when counting up and down

Compare B Compare Match When the count value is equal to CCRxB, different channels can be controlled individually using CRCHx.CISB.

When CRCHx.CISB=2'b00 Channel x compare match no output

When CRCHx.CISB=2'b01 compare match while counting on channel x

When CRCHx.CISB=2'b10 Compare match when counting down channel x

When CRCHx.CISB=2'b11 Comparing matches when channel x counts up and down

The B channel comparison match is controlled separately for more flexible triggering of the ADC.

For details, refer to the Timer Trigger ADC chapter.

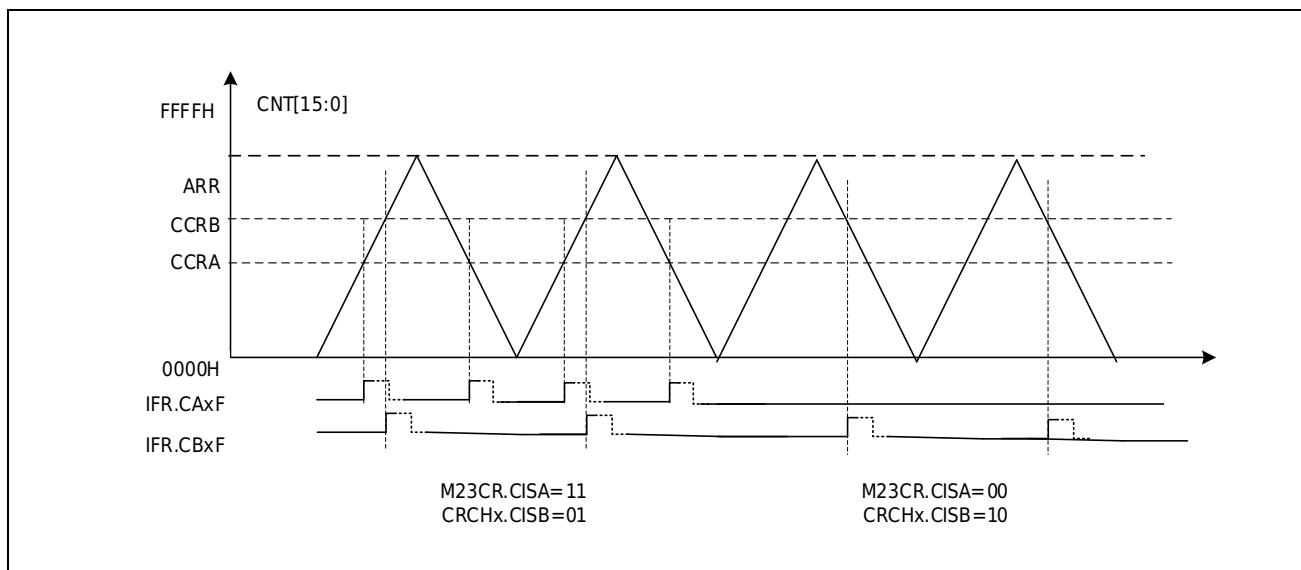

Figure 14-46 Interrupt diagram

14.2.6.11 Capture input

CR.MODE=2/3

The capture function can be set in the triangular wave counting or sawtooth wave counting mode, and the level edge of the capture can be set. When the capture occurs, the captured value is stored in the comparison capture register and a capture interrupt is generated.

The compare capture function of each channel can be set individually, selected by the register CRCHx.CSA/CSB.

The edge of the capture trigger can be selected through the register CRCHx.CFy/CRy ($x=0/1/2; y=A/B$).

When the capture action occurs again before the capture flag is cleared after the capture occurs, the capture data overwrite flag will be generated.

When the timer is not started, if there is a valid capture edge, the capture flag and capture action will also be generated.

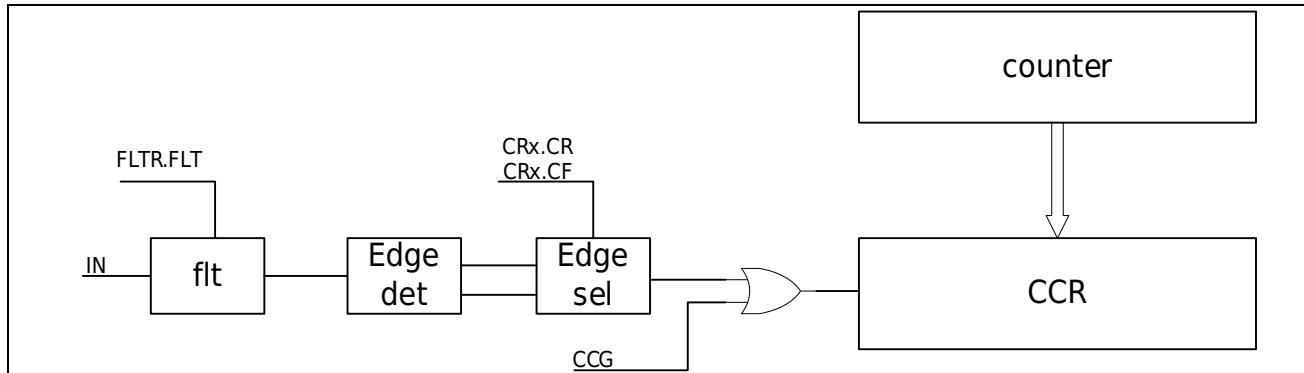

Figure 14-47 Capturing Functional Block Diagram

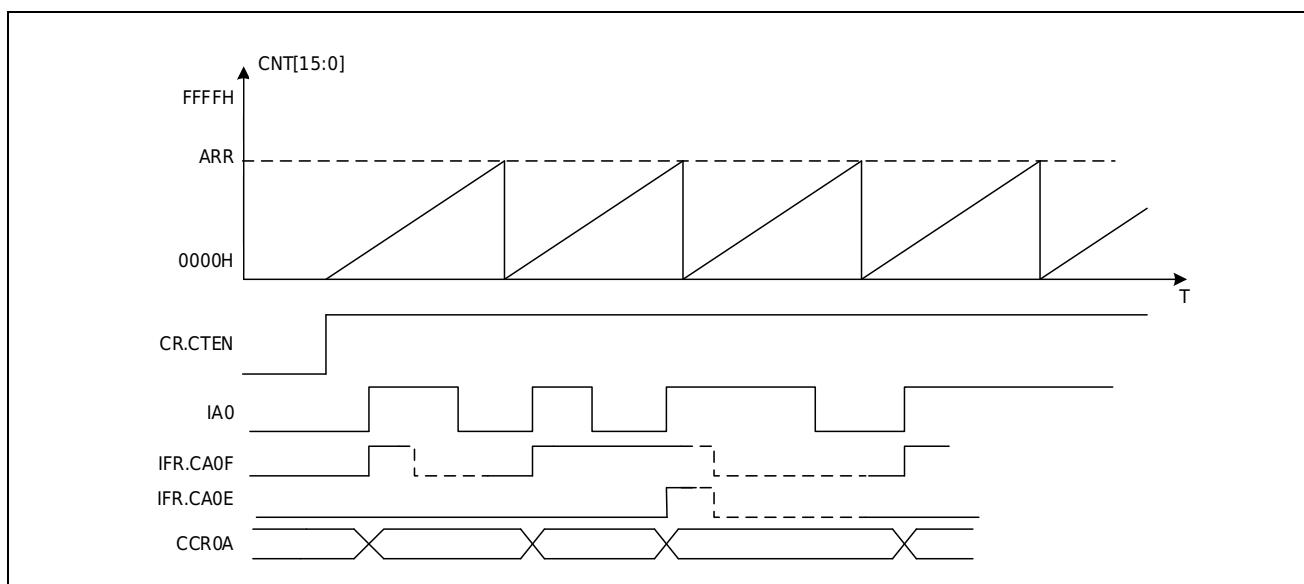

Figure 14-48 Capture Timing Diagram

CH0A selects CH0A input or the XOR input of CH0A, CH1A, and CH2A through MSCR.IA0S.

IA0S	0	1
Timer0/1/2	CHA0	CHA0 ETR GATE XOR input
Timer3	CHA0	CHA0 CHA CHA2 XOR input

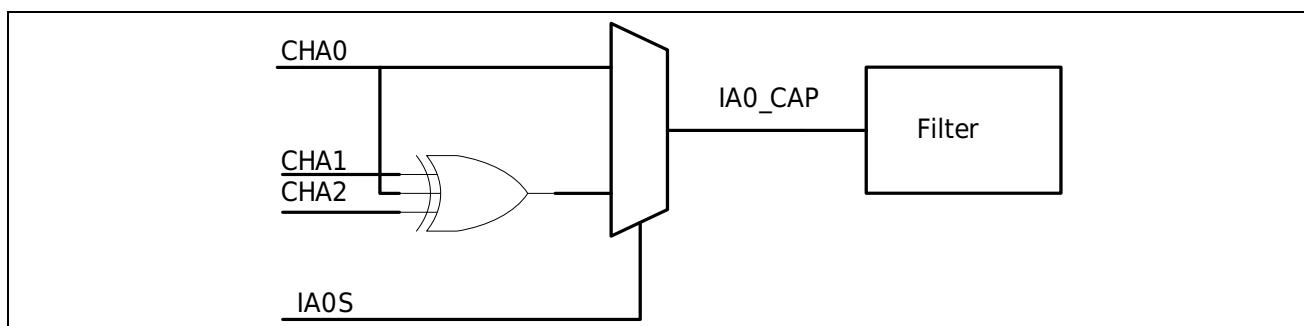

Figure 14-49 CHA port selection

The capture input of CH0B is selected by MSCR.IB0S as input to CH0B or the signal selected by content MSCR.TS.

IB0S	0	1
Timer0/1/2/3	CHB0	Internal trigger MSCR.TS select signal
		MCSCR.TS Channel B capture input
		000 ETR filter phase selection output signal, filter phase selection can be configured
		001 Interconnect ITR0
		010 Interconnect ITR1
		011 Interconnect ITR2
		100 Interconnect ITR3
		101 CH0A edge
		110 CH0A filter output signal, filter function can be configured
		111 CH0B filter output signal, filter function can be configured

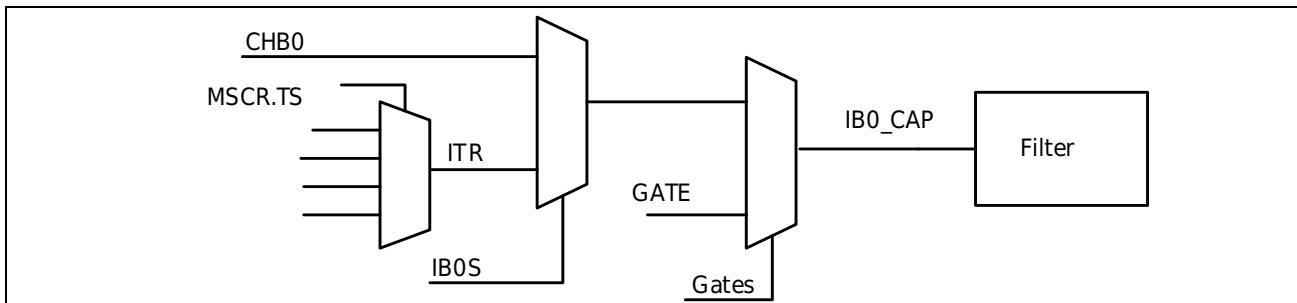

Figure 14-50 CHB port selection

The Gates signal is a signal generated by selecting the PWM complementary output function. When the PWM complementary output is used, the comparison capture register CCR0B is not used, and it is automatically switched to use GATE as the capture / comparison output.

14.2.6.12 Setup example

Edge-Aligned Independent PWM Output Settings

1. Set mode CR.MODE=2
2. Set the sawtooth wave counting direction CR.DIR
3. Set PWM period value ARR
4. Set the initial value of the counter (the initial value must be less than the period value)
5. Set PWM comparison value CCRxA, CCRxB
6. Set PWM output comparison mode FLT.OCMA FLT.OCMB to 6 or 7
7. Clear the associated interrupt flag
8. Enable the corresponding interrupt

9. Set output polarity FLT.CCPAx FLT.CCPBx
10. Enable output DTR.MOE
11. Enable timer CR.CTEN

Center-Aligned Complementary PWM Output Settings

1. Set mode CR.MODE=3
2. Set Complementary Output CR.COMP
3. Set PWM period value ARR
4. Set the initial value of the counter (the initial value must be less than the period value)
5. Set the PWM comparison value CCRxA (CCRxB does not need to be set, the PWM output has nothing to do with this register)
6. Set PWM output comparison mode FLT.OCMA FLT.OCMB to 6 or 7
7. Clear the associated interrupt flag
8. Enable the corresponding interrupt
9. Set output polarity FLT.CCPAx FLT.CCPBx
10. Enable output DTR.MOE
11. Enable timer CR.CTEN

Triangular wave non-center alignment with dead zone complementary PWM output setting

1. Set mode CR.MODE=3
2. Set Complementary Output CR.COMP
3. Set two compare enable CR.PWM2S
4. Set PWM period value ARR
5. Set the initial value of the counter (the initial value must be less than the period value)
6. Set the PWM comparison value CCRxA, CCRxB, the upper counting comparison point is CCRxA, and the lower counting comparison point is CCRxB
7. Set PWM output comparison mode FLT.OCMA FLT.OCMB to 6 or 7
8. Clear the associated interrupt flag
9. Enable the corresponding interrupt
10. Set output polarity FLT.CCPAx FLT.CCPBx
11. Set dead zone enable DTR.DTEN
12. Set dead time DTR.DT
13. Enable output DTR.MOE
14. Enable timer CR.CTEN

Capture function settings

Set CH0B as rising edge capture function

1. Select the counter counting method, set mode=2
2. Select CH0B as capture mode CRCHx.CSB=1
3. FLT.FLTB0 as required
4. Select the captured edge CRCHx.CRB=1
5. Set ARR to change the period value
6. Start timer CR.CTEN
7. Clear the associated interrupt flag
8. Clear the capture flag and enable the corresponding interrupt
9. After querying the capture flag, read CCR0B to obtain the capture value

Note: If the capture edge is valid when the timer is not started, the capture flag and capture action will also be generated.

Complementary PWM output uses GATE as PWM output function

1. Set to PWM complementary output mode, refer to " Center Aligned Complementary PWM Output Setting "
2. Set CCR0B to set GATE PWM comparison value
3. Set FLT.OCMB0=6/7 to set PWM output mode
4. Enable PWM output DTR.MOE

Complementary PWM output uses GATE falling edge as capture input function

1. Set to PWM complementary output mode, refer to " Center Aligned Complementary PWM Output Setting "
2. Set GATE as capture input CR.CSG
3. Select GATE to capture the input edge and set CR.CFG (GATE is used as the capture input B channel filter setting is invalid)
4. Start timer CR.CTEN
5. Clear the associated interrupt flag
6. Clear the capture flag and enable the corresponding interrupt
7. After querying the capture flag, read CCR0B to obtain the capture value

14.2.7 Mode 2/3 Slave Mode

The timer can be synchronized to an external trigger in several modes: reset mode, gated mode and triggered mode.

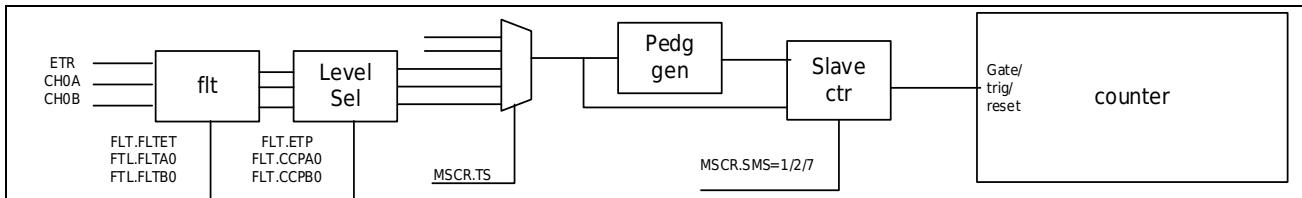

Figure 14-51 Slave Mode Schematic

Select from mode function by MSCR.SMS;

MSCR.SMS	Select from mode function 001: Reset function; 010: Trigger mode; 111: Gating function
MSCR.TS	Trigger selection 000: The signal ETP after the filter phase selection of port ETR, the filter function can be configured 001: Internal interconnection signal ITR0 010: internal interconnection signal ITR1; 011: internal interconnection signal ITR2; 100: internal interconnection signal ITR3; 101: edge signal of port CH0A; 110: Port CH0A filters the signal IAFP after phase selection, the filter function can be configured 111: The signal IBFP after the filter phase selection of port CH0B, the filter function can be configured

14.2.7.1 Gated count

Enables the counter according to the selected input level. In the following example, the counter only counts up when CH0A is low:

- Configure channel CH0A to detect a low level on CH0A. Configure the input filter bandwidth (in this example, no filtering is required, so keep FLT.FLTA0=000). Set CCPA0=1 in the FLTR register to determine the polarity (only detect low level).
- Set SMS=111 in the SMCR register to configure the timer as gated mode; set TS=110 in the SMCR register to select CH0A as the input source.
- Set CTEN=1 in the CR register to start the counter. In gated mode, if CTEN=0, the counter cannot be started regardless of the trigger input level. As long as CH0A is low, the counter starts counting according to the internal clock, and stops counting once CH0A becomes high.

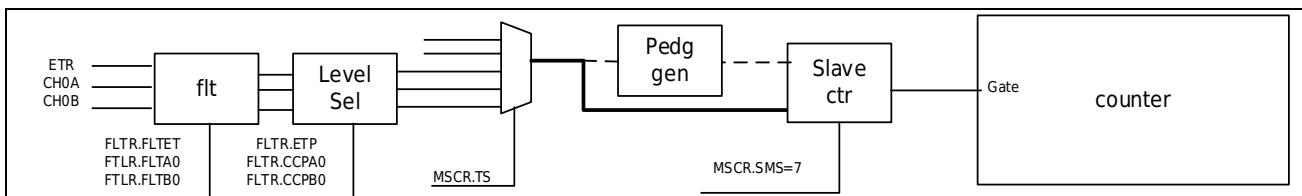

Figure 14-52 Gating function

14.2.7.2 trigger function

Using external triggers (CH0A, CH0B, ETR) can start the timer synchronously, and using the internal interconnection signal of the timer combined with MSCR.MSM can also configure the timer to start synchronously. The trigger signal is the rising edge of the input signal. You can also use software to write CR.TG to start the software trigger function.

A selected event on the input enables the counter. In the example below, the counter starts counting up on the rising edge of the CH0B input:

- Configure channel CH0B to detect the rising edge of CH0B. Configure the input filter bandwidth (in this example, no filter is needed, keep FLT.FLTB0=000). Set CCPB0=0 in the FLTR register to determine the polarity (no inversion).
- Set SMS=010 in the SMCR register to configure the timer as trigger mode; set TS=111 in the SMCR register to select CH0B as the input source. When a rising edge appears on CH0B, the counter starts counting driven by the internal clock and sets the TIF flag at the same time. The delay between the rising edge of CH0B and the start of the counter depends on the resynchronization circuit at the CH0B input.

Note: If you use the falling edge trigger, first select the trigger polarity, and then select the mode, otherwise false triggers will occur.

14.2.7.3 reset count

When a trigger input event occurs, the counter and its prescaler can be re-initialized; at the same time, if the URS bit of the CR register is low, an update event UEV is also generated; then all preload registers (ARR, CCRx) are updated.

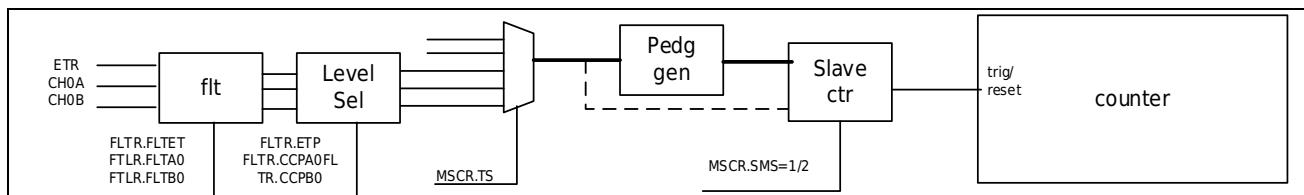

Figure 14-53 Trigger and reset functions

14.2.8 Quadrature code counting function

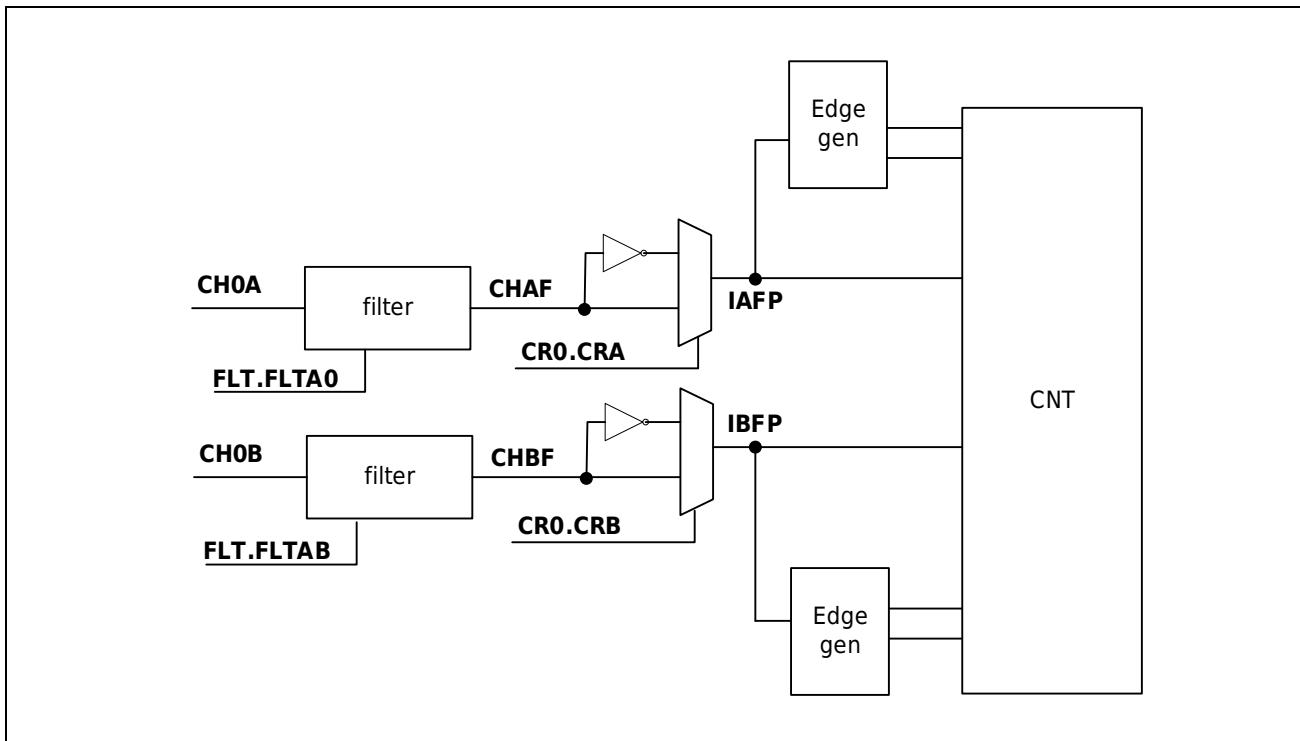

MSCR.SMS=4/5/6, corresponding to the mode 1/2/3 of the orthogonal coding mode. At this time, the counter encodes and counts according to the phase relationship of IAfp and IBfp. IAfp, IBfp is the port input CH0A, CH0B filter phase selection signal.

Mode 1 uses the edge count of CH0A. Mode 2 uses the edge count of CH0B. Mode 3 uses both CH0A and CH0B edges to count.

In order to ensure the correctness of the counting phase, it is necessary to ensure that the phase difference of the A/B input is greater than the phase difference of one pulse width, and the A/B input pulse width needs to be greater than two pulse widths.

			IAFP		IBFP	
	IBFP	IAFP	Rising	falling	Rising	falling
MOD1	High		Down	Up	-	-
	Low		up	Down	-	-
MOD2		High	-	-	up	Down
		Low	-	-	Down	Up
MOD3	High	High	Down	Up	up	Down
	Low	Low	up	Down	Down	Up

CHAF/CHBF is the signal filtered by port CH0A/CH0B, and IAFP/IBFP is the signal after port filter phase selection.

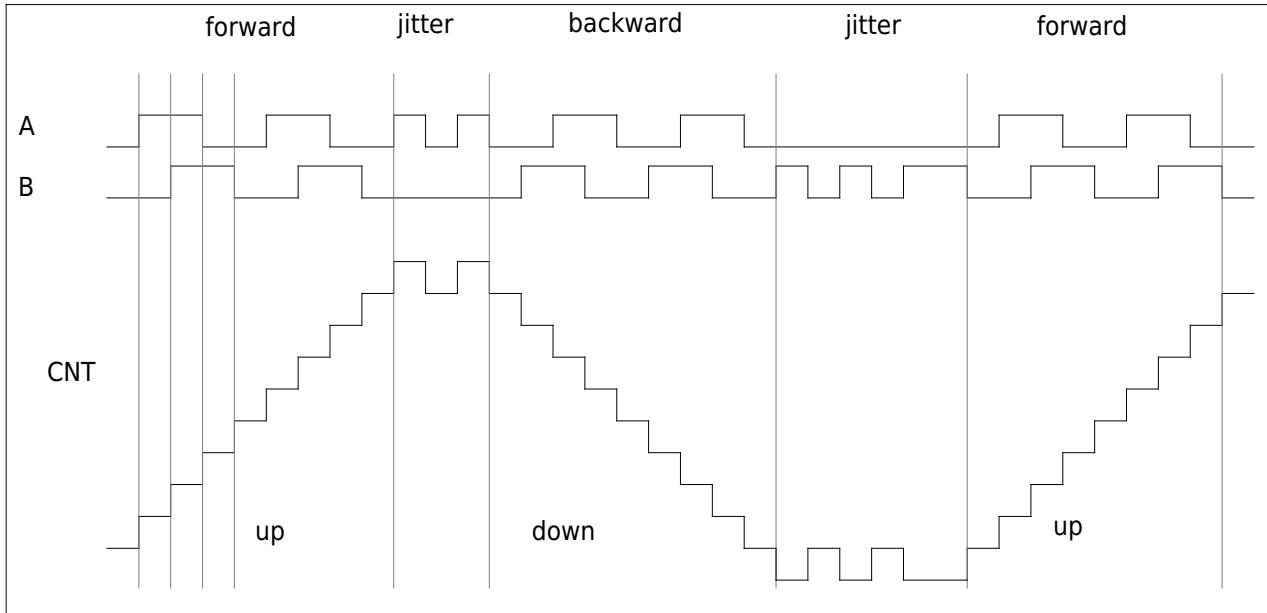

Figure 14-54 Code count

14.2.9 Timer triggers ADC

CCMR0A, CCMR1A, CCMR2A comparison match can be configured to trigger ADC, and center-aligned PWM can only be selected through the control register CR.CIS to trigger on rising match or falling match.

CCMR0B, CCMR1B, CCMR2B comparison match can be configured to trigger ADC. When center-aligned PWM, three matching trigger points (rising, falling, rising and falling) can be controlled respectively through the register CRx.CISB.

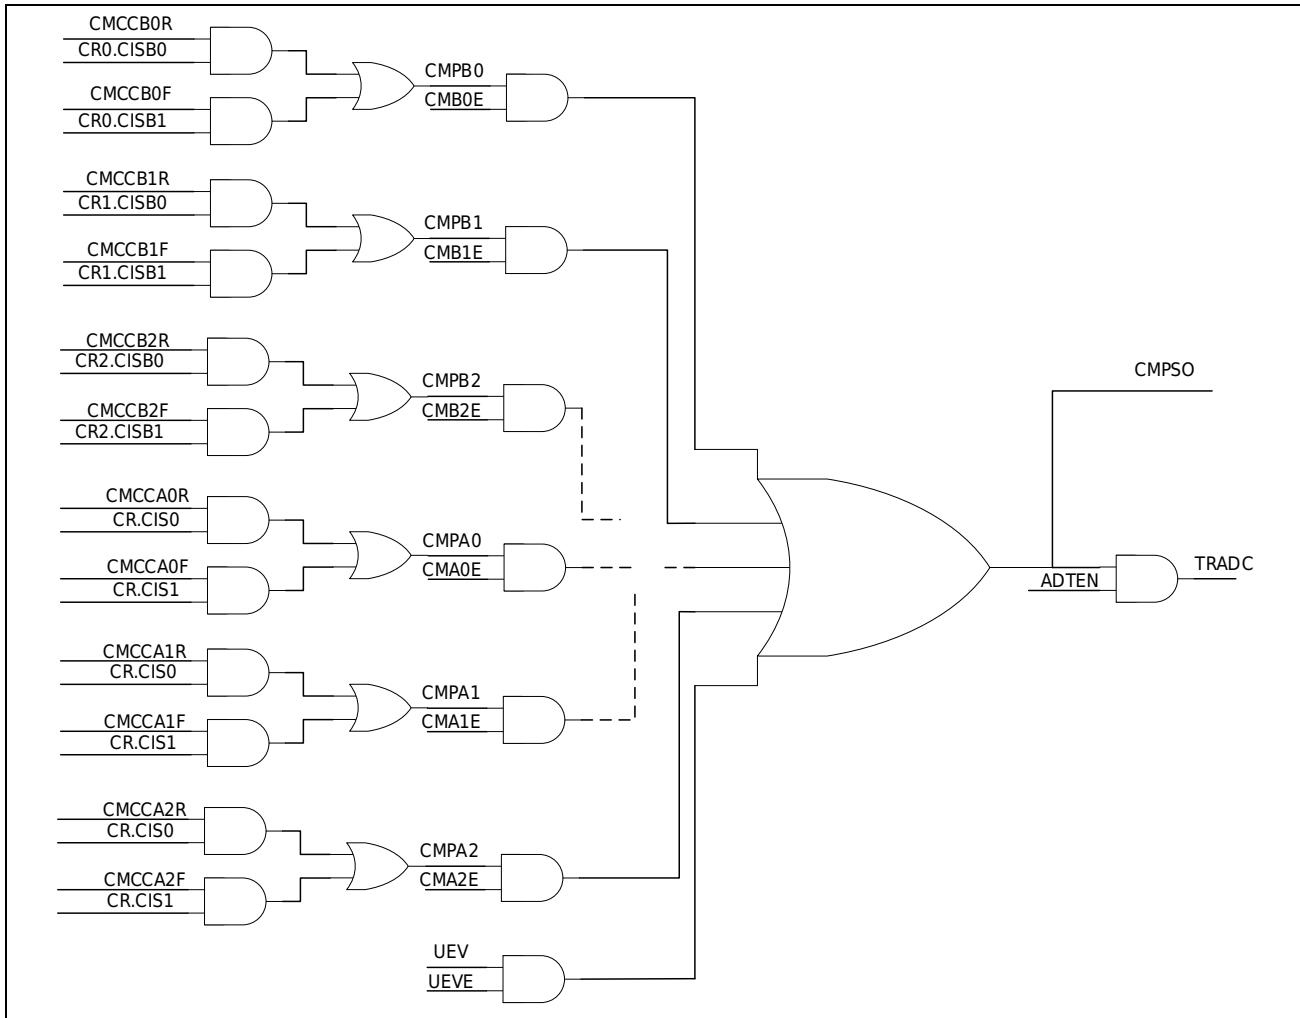

Figure 14-55 ADC trigger

Complementary PWM output B compare as ADC trigger function

1. Set to PWM complementary output mode, refer to "Center Aligned Complementary PWM Output Setting"
2. Set CCRxB to set ADC trigger comparison point
3. Set CRCHx.CISB to select up-counting and down-counting comparison matching (sawtooth wave does not need to be selected)
4. Select the source ADTR for ADC trigger comparison
5. Enable ADC trigger ADTR.ADTE

14.2.10 Brake control

The VC comparison output can control the braking function, the external BK port input can control the braking function, and the system fail can control the braking function. Through CR.BG, the software brake function can be realized, and the output port can be controlled to the set state.

The two-channel output Tim0/1/2 can choose to use the brake port of Tim0 to control the brake function of TIM1/2, or use their own brake input to control their respective brake functions. When DTR.BKSEL is set to 1, TIM1/2 share the brake input of TIM0.

14.2.11 Timer interconnection

The TRGO output signal can be connected to the ITR signal of other timers. The connection relationship is as follows:

	ITR0	ITR1	ITR2	ITR3
Timer0	-	TIM1_TRGO	TIM2_TRGO	TIM3_TRGO
Timer1	TIM0_TRGO	-	TIM2_TRGO	TIM3_TRGO
Timer2	TIM0_TRGO	TIM1_TRGO	-	TIM3_TRGO
Timer3	TIM0_TRGO	TIM1_TRGO	TIM2_TRGO	-

Timer TIM0/1/2 start PWM output setting at the same time (use CTEN of TIM0 to trigger TIM1/2) example

1. Refer to the PWM output setting to set the pulse adjustment output of timer 0/1/2
2. Set TIM0 as master mode MSCR.MSM=1
3. Set CTEN of TIM0 to trigger the other two timers MSCR.MMS=1
4. Keep MSCR.MSM=0 of TIM1/2
5. Set TIM1/2 as trigger mode MSCR.SMS=2
6. Select the trigger source of TIM1/2 as TRGO of TIM0, MSCR.TS=1
7. Finally enable the timer TIM0, start the timer CR.CTEN=1

Timer TIM0/1/2 start PWM output setting at the same time (use UG of TIM1 to trigger TIM0/2) example

1. Refer to the PWM output setting to set the pulse adjustment output of timer 0/1/2
2. Set TIM1 to trigger master mode MSCR.MSM=1
3. Set the UG of TIM1 to trigger the other two timers MSCR.MMS=0
4. Keep MSCR.MSM=0 of TIM0/2
5. Set TIM0/2 as trigger mode MSCR.SMS=2
6. Select the trigger source of TIM0/2 as TRGO of TIM0, MSCR.TS=2
7. Finally enable the timer TIM1, start the timer CR.UG=1

14.2.12 GATE input interconnection

The GATE input can be directly input from the port through PX_SEL, or it can be connected to other modules or ports through the port function register GPIO_TIMGS.

When TIMx_G=0x0, the gate control GATE input is the port input selected by PX_SEL. When TIMx_G=0x1~0x7, it is connected to the input or output of other modules.

	TIM0_g	TIM1_g	TIM2_g	TIM3_g
000	PX_SEL	PX_SEL	PX_SEL	PX_SEL
001	UART0_RXD	LPUART0_RXD	UART0_RXD	UART0_RXD
010	UART1_RXD	LPUART1_RXD	UART1_RXD	UART1_RXD
011	VC0_OUT	VC0_OUT	VC0_OUT	LPUART0
100	VC1_OUT	VC1_OUT	VC1_OUT	LPUART1
101	PA03	PA08	PA10	VC0_OUT
110	PB08	PB03	PB04	PA06
111	PB15	PB13	PB11	PA11

14.2.13 ETR input interconnection

ETR input can be directly input from the port, or can be connected to other modules or ports through the selection of the port function register GPIO_TIMES.

When TIMx_E=0x0, the external clock EXT input is the port input selected by PX_SEL. When TIMx_E=0x1~0x7, it is connected to the input or output of other modules.

	TIM0_e	TIM1_e	TIM2_e	TIM3_e
000	PX_SEL	PX_SEL	PX_SEL	PX_SEL
001	LPUART0_RXD	UART0_RXD	LPUART0_RXD	UART0_RXD
010	LPUART1_RXD	UART1_RXD	LPUART1_RXD	UART1_RXD
011	VC0_OUT	VC1_OUT	VC0_OUT	VC1_OUT
100	LVD_OUT	LVD_OUT	Reserved	Reserved
101	PA00	PA01	PA04	PA00
110	PA05	PC09	PC04	PA12
111	PA15	PD02	PC08	PA13

14.2.14 CHx capture input interconnect

The CHA of Timer0/1/2 and the CH0A/CH0B input of Timer3 can be directly input from the port, or can be connected to other modules or ports through the selection of the port function register GPIO_TIMCPS.

	TIM0_CHA	TIM1_CHA	TIM2_CHA	TIM3_CH0A	TIM3_CH0B
000	PX_SEL	PX_SEL	PX_SEL	PX_SEL	PX_SEL
001	UART0_RXD	UART1_RXD	LPUART0_RXD	LPUART1_RXD	UART0_RXD
010	PA00	PA00	VC0_OUT	LPUART0_RXD	UART1_RXD
011	PA02	PA02	PA02	Reserved	Reserved
100	PA05	PA06	PA07	VC0_OUT	VC1_OUT
101	PA15	PB08	PB08	PA08	PA07
110	PB06	PB10	PB09	PB03	PB04
111	PB14	PB13	PC06	PB06	PB13

When $\text{TIMx_CHy}=0x0$, the capture input is the port input selected by PX_SEL . When $\text{TIMx_CHy}=0x1\sim0x7$, it is connected to the input or output of other modules.

14.2.15 DMA

Timer supports software and hardware to trigger DMA for data transfer. Data is supported to be written to the timer from other locations, or read and written from the timer to other locations. It can be applied to the automatic handling of data after data capture and the automatic adjustment of the pulse width changing the period value or duty cycle. Each timer has two DMA requests, A request trigger source can choose compare capture A, external trigger, B request trigger source can choose compare capture B, event update.

IDREQ	Interrupt Signal of Peripheral
18	TIM0A
19	TIM0B
20	TIM1A
21	TIM1B
22	TIM2A
23	TIM2B
24	TIM3A
25	TIM3B

TIMxA can choose compare capture A, ETRIG

TIMxB can be selected to compare capture B, UEV

14.2.15.1 Setup example

Capture data DMA data transmission

1. enable DMA
2. Enable DMA channel enable
3. Select the channel for timer DMA
4. Set the transmission type, transmission length, transmission method
5. Set source start address, destination start address
6. Set the increment mode of source address and destination address
7. Enable DMA interrupts as needed
8. Set up data capture with reference to the data capture process
9. Enable CRCHx.CDy enables capture data to trigger DAM transfer.

Note: The source address is set to the capture channel register, the source address is fixed, and the destination address is added.

Pulse adjusted DMA data transfer

1. enable DMA
2. Enable DMA channel enable
3. Select the channel for timer DMA
4. Set the transmission type, transmission length, transmission method
5. Set source start address, destination start address
6. Set the increment mode of source address and destination address
7. Enable DMA interrupts as needed
8. Reference Pulse Adjustment Output Setting Pulse Modulation Output
9. Select the condition of hardware triggering DMA according to needs (UEV trigger or comparison match trigger)

Note: The target address is set as the capture channel register, the source address changes, and the target address is fixed.

14.3 Timer register description

Table 14-1 Timer register list

Timer	base address	Description
Timer0	0x40000C00	Timer0基地址
Timer1	0x40000D00	Timer1基地址
Timer2	0x40000E00	Timer2基地址
Timer3	0X40005800	Timer3基地址

Register	Offset address	Description
TIMx_ARR	0X000	Timer reload register / cycle
TIMx_CNT	0X004	Timer 16 -bit mode count register
TIMx_CNT32	0X008	Timer 32 -bit mode count register Note: TIMx_CNT32 is the remapping register of TIMx_ARR and TIMx_CNT. In order to facilitate the 32 -bit timer write operation.
TIMx_M0CR	0X00C	Timer mode 0 control register (described by different modes)
TIMx_M1CR	0X00C	Timer mode 1 control register (described in different modes)
TIMx_M23CR	0X00C	Timer mode 23 control register (described in different modes)
TIMx_IFR	0X010	Timer interrupt flag
TIMx_ICLR	0X014	Timer interrupt clear register
TIMx_MSCR	0X018	Master-slave mode control
TIMx_FLTR	0X01c	Filter control
TIMx_ADTR	0X020	ADC trigger control
TIMx_CRCH0	0x024	Compare Unit 0 Control Register
TIMx_CRCH1	0X028	Compare Unit 1 Control Register
TIMx_CRCH2	0x02C	Compare Unit 2 Control Register
TIMx_DTR	0X030	Dead zone register
TIMx_RCR	0X034	Repeat Count Register
TIMx_ARRDM	0X038	Timer reload register / period map address
TIMx_CR0	0x024	control register
TIMx_CCR0A	0X03C	Compare 0A Register
TIMx_CCR0B	0x040	Compare 0B register
TIMx_CCR1A	0X044	Compare 1A Register
TIMx_CCR1B	0X048	Compare 1B Register
TIMx_CCR2A	0X04C	Compare 2A Register
TIMx_CCR2B	0X050	Compare 2B register

14.4 Mode 0 Timer Register Description

BUFPEN	PRS			Pwm2s	CT	Comp	CTEN
RW	RW			RW	RW	RW	RW
Bit	Symbol	Description					
31:28	Reserved	Reserved bit					
27	DIR	Counting direction, can only be written in sawtooth wave mode. Read-only in other modes, invalid for writing 0: count up 1: count down Note: DIR is automatically cleared to 0 when switching from other modes to center-aligned mode. DIR is automatically cleared in reset mode by software event update and external trigger in slave mode.					
26	BG	Software brake, automatic reset Write 1 to generate software brake; Writing 0 is invalid					
25	UG	Software update, automatic reset Write 1 to generate software update; Writing 0 is invalid Initialize the counter and update the cache register to the corresponding register (cache enable), the pre-divider counter will also be cleared.					
24	TG	Triggered by software, automatically cleared, it needs to be triggered under the trigger mode SMS=2 and mode=2/3. Write 1 to generate software trigger; Writing 0 is invalid					
23	OCCE	OCREF clear enable 1: OCREF_CLR signal can clear OCREF output 0: OCREF output is not affected by OCREF CLR					
22:21	CIS	Center-aligned A compare interrupt mode (B compare interrupt is controlled separately in CRx register CISB) 00: no interrupt, 01: rising edge interrupt, 10: Falling edge interrupt, 11: Both the upper and lower edges are interrupted					
20	BIE	Brake Interrupt Enable 1: interrupt enable 0: interrupt disabled					
19	TIE	Trigger interrupt enable 1: interrupt enable 0: interrupt disabled					
18	TDE	Trigger DMA enable 1: interrupt enable 0: interrupt disabled					

17	URS	Update source 0: overflow / underflow / software update UG/ slave mode reset; 1: overflow / underflow
16	OCCS	OCREF Clear Source Selection 0: Voltage comparator VC output, VC selection is set in VCx_OUTCFG register 1: ETR port filters the signal after phase selection When OCCE is valid, OC_clr can clear the comparison output signal of OCREF to zero, (valid when OCMx>1), and continue to compare the output after the next uev event
15	CSG	GATE capture / comparison selection in PWM complementary mode; (only valid in PWM complementary output) Use CCR0B as compare or capture channel for GATE 1: capture; 0: Compare
14	Oneshot	Single trigger mode selection 1: Timer stops after an event update occurs. 0: loop count
13:12	MODE	Operating mode 00 Timer mode 0; 01 PWC mode 10 sawtooth wave mode; 11 triangle wave mode
11	UDE	update DMA enable 1: Enable update triggered DMA 0: disable update trigger DMA
10	UIE	UIE update interrupt enable 1: enable update interrupt 0: disable update interrupt
9	CFG	When GATE is used as a capture input, the falling edge capture is effectively controlled (only valid when PWM complementary output) 1: Falling edge capture is valid 0: Falling edge capture is invalid
8	CRG	GATE is used as a capture input, the rising edge capture is effectively controlled (only valid when PWM complementary output) 1: The upper edge capture is valid 0: The rising edge capture is invalid
7	BUFPEN	reload cache enable 1: The period cache is enabled, and the period value will not be affected until the next event is updated after writing. 0: The period cache is invalid, and the period value will be affected immediately after writing
6:4	PRS	Internal clock frequency division selection 000: 1; 001: 2; 010: 4; 011: 8; 100: 16; 101: 32; 110: 64; 111: 256;
3	PWM2S	OCREFA two-point comparison selection (default is 1) 0: Dual-point comparison is enabled, use CCRA, CCRB comparison to control OCREFA output 1: Single-point compare enable, only use CCRA compare to control OCREFA output Note: OCREFB is not affected, still use CCRB to control OCREFB output
2	CT	Counting clock selection 0: Internal count clock TCLK 1: External count clock ETR;
1	Comp	PWM complementary output mode selection 0: independent PWM output 1: Complementary PWM output
0	CTEN	Timer enable 0: forbidden; 1: Enable It can be enabled by external trigger, and this bit is automatically cleared at the end of oneshot mode

15 Programmable Count Array (PCA)

15.1 Introduction to PCA

PCA (Programmable Counter Array) supports up to 5 16-bit capture/compare modules. The timer/counter can be used as a common clock count/event counter capture/compare function. Each module of PCA can be independently programmed to provide input capture, output comparison or pulse width modulation. In addition, module 4 has an additional watchdog timer mode.

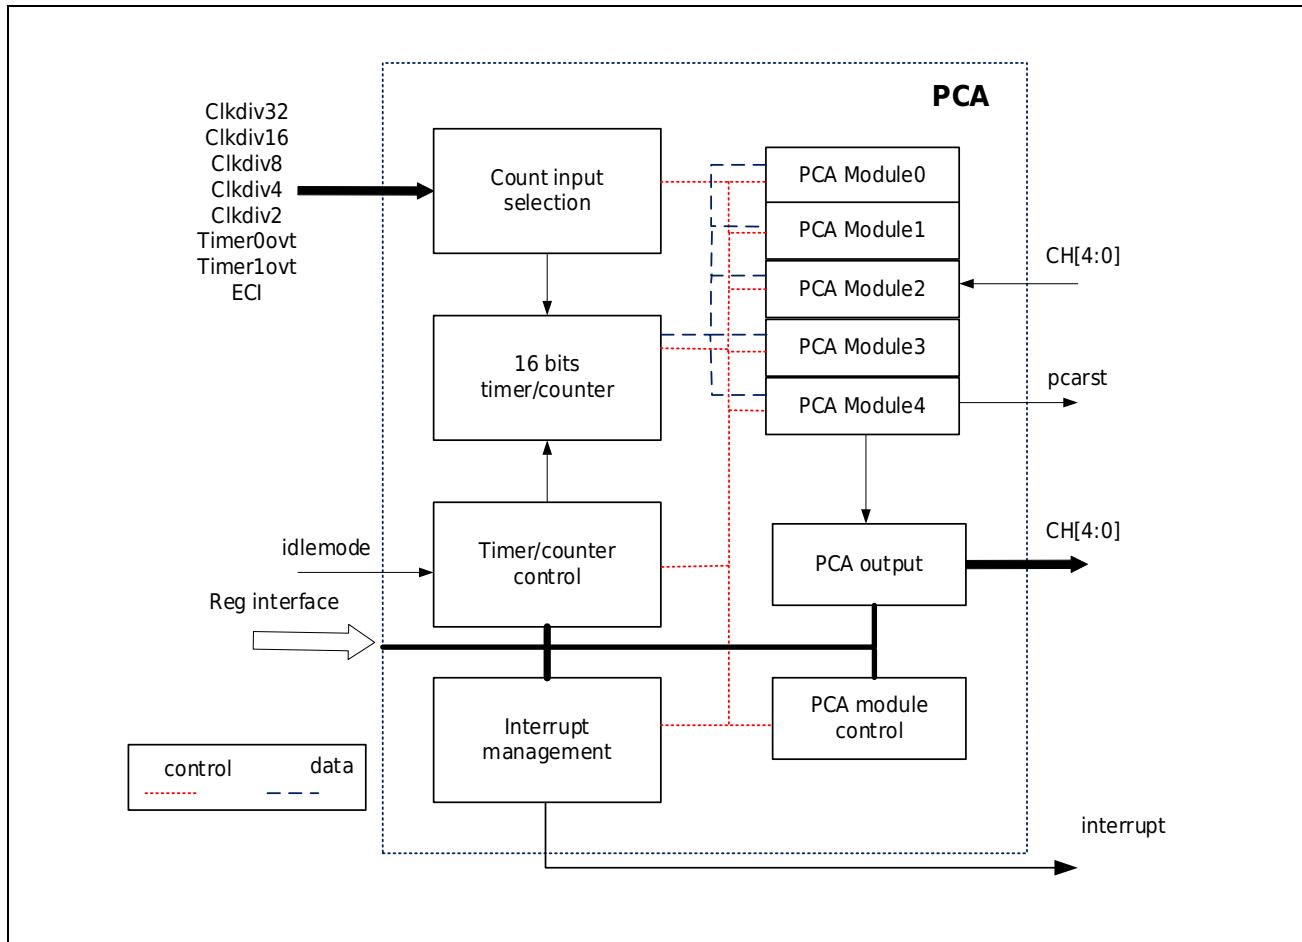

Figure 15-1 Overall block diagram of PCA

15.2 PCA function description

All five modules can be configured to work independently, and there are three working modes: edge-triggered capture, output comparison, and 8/16-bit pulse width modulation. Each module has its own function registers in the system controller, and these registers are used to configure the working mode of the module and exchange data with the module.

Each comparison / capture module is composed of a comparison / capture register group (CCAPx), a 16-bit comparator, and various logic gate controls. The register group is used to store time or times, for external trigger capture conditions, or internal trigger comparison conditions. In 8-bit PWM mode, the register (CCAPxL) is used to control the duty cycle of the output waveform, and

CCAPxH is an 8-bit compare buffer. In 16-bit PWM mode, CARR is used to control the period of PWM output, and the CCAPx register controls the duty cycle.

Each module can be independently programmed to operate in any of the following modes:

- 16-bit capture mode.
- Compare mode: 16-bit high-speed output, 16-bit watchdog timer (module 4) or 16/8-bit PWM.
- Disabled.

The Compare / Capture Module Mode Registers (CCAPMx) determine the corresponding operating mode. When programming the compare / capture modules, they are based on a common time count. The timer / counter is turned on and off through the CCON.CR bit to control the operation of the PCA timer / counter. On a compare / capture module capture, the software timer, high-speed output, sets the module's compare / capture flag (CCON.CCFx), and generates a PCA interrupt request if the corresponding enable bit is set in the CCAPMx register. The CPU can read and write the CCAPx registers at any time.

15.2.1 PCA Timer / Counter

This group of special function registers of CNT can be used as a 16-bit timer / counter. This is a 16-bit up counter. If the CMOD.CFIE bit is set to "1", when the CNT overflows, the hardware automatically sets the PCA overflow flag (CCON.CF) and generates a PCA interrupt request. Three bits of CMOD.CPS[2:0] select eight signals to be input to the timer/counter.

- The system clock PCLK is divided by 32.
- The system clock PCLK is divided by 16.
- The system clock PCLK is divided by 8.
- The system clock PCLK is divided by 4.
- The system clock PCLK is divided by 2.
- Timer 0 overflow. CNT is incremented each time Timer 0 overflows, thus providing a variable programming frequency input to the PCA.
- Timer 1 overflow. CNT is incremented each time Timer 1 overflows, thus providing a variable programming frequency input to the PCA.
- ECI. The CPU samples the PCA ECI every 4 PCLK clock cycles. When the sampling result changes from high to low each time, CL is automatically incremented by 1. Therefore, the highest ECI input frequency cannot be higher than 1/8 of the system clock PCLK to meet Sampling requirements.

Set the run controller (CCON.CR) to start the PCA timer / counter. When CMOD.CIDL is set to "1", the PCA timer / counter can continue to run in idle mode. The CPU can read the value of CNT at any time, but when the count is started (CCON.CR=1), in order to prevent counting errors, CNT is prohibited from being written.

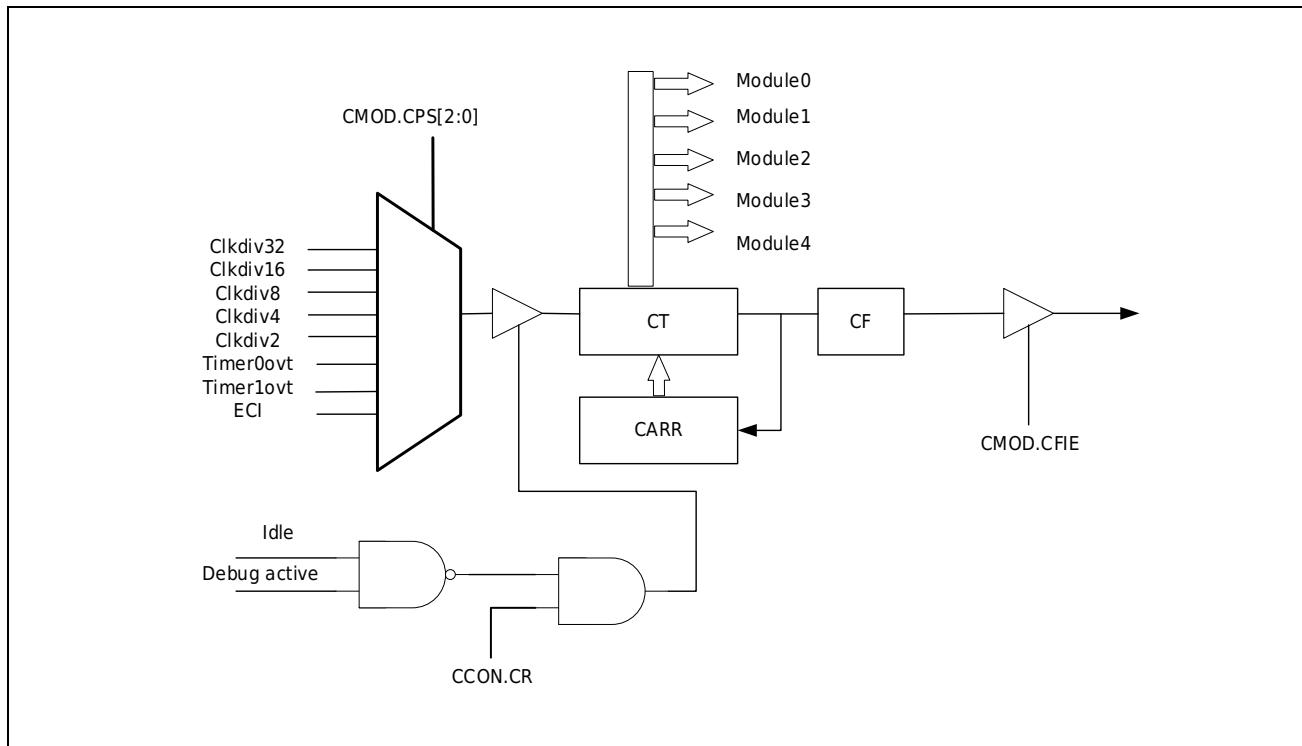

Figure 15-2 PCA Counter Block Diagram

15.2.1.1 16 -bit free count mode

After the counter counts to the maximum value of 0xFFFF and overflows, the value of the counter becomes 0 and starts counting up again. If you need to change the counting period value, you can stop PCA to change the initial value of the counter and continue counting. Can be used in PCA capture mode, 8-bit PWM mode.

Setup process

1. Keep the EPMW of PCA_EPWM as 0
2. Set PCA_CMOD.CPS to select the count clock
3. PCA_CMOD.CFIE to enable count overflow interrupt as required
4. Clock PCA_CCON.CR starts the PCA counter
5. Overflow to change the initial value of the counter needs to stop the PCA counter

15.2.1.2 16 -bit reload count mode

When the counter counts to the same value as the register CARR, the value of the counter overflows and becomes 0, and continues to count up. It can be used in PCA capture mode and 16 -bit PWM mode.

Setup process

1. Set the EPMW of PCA_EPWM to 1
2. Set PCA_CARR to set the count period value
3. Set PCA_CMOD.CPS to select the count clock

4. PCA_CMOD.CFIE to enable count overflow interrupt as required
5. Clock PCA_CCON.CR starts the PCA counter

15.2.2 PCA capture function

PCA capture mode provides 5-way PCA to measure pulse period, pulse width, duty cycle and phase difference.

A level transition on the pin causes the PCA to capture the value of the PCA counter / timer and load it into the corresponding module's 16-bit capture / compare register (CCAPx). The CCAPMx.CAPP and CCAPMx.CAPN bits are used to select the type of level change that triggers the capture: low to high (positive edge), high to low (negative edge), or any change (positive or negative edge) along. When a capture occurs, the Capture / Compare Flag (CCFn) in CCON is set to logic '1' and an interrupt request is generated (if CCF interrupts are enabled). When the CPU turns to the interrupt service routine, the CCFn bit cannot be automatically cleared by hardware, and the user software can write the INTCL register to clear this flag bit. If the CCPMx.CAPP and CCAPMx.CAPN bits are both set to logic '1', you can directly read the state of the corresponding port pin to determine whether the capture is triggered by a rising edge or a falling edge.

The resolution is equal to the clock of the timer / counter. 2 clock cycles during the high level or low level to ensure that the input signal can be recognized by the hardware.

The CPU can read or write the CCAPx registers at any time.

Capture settings:

- When capturing on an external rising edge is required, CCPMx.CAPP = "1" and CCAPMx.CAPN = "0"
- When capturing on an external falling edge is required, CCPMx.CAPP = "0" and CCAPMx.CAPN = "1"
- When capture is required on external rising and falling edges, CCPMx.CAPP = "1" and CCAPMx.CAPN = "1"
- Configure capture interrupts and interrupt handlers as required.
- PCA counter to start according to the timer / counter.

Note:

- Subsequent captures by the same module override existing captured values. In order to keep the captured value, save it in RAM in the interrupt service routine, this operation must be completed before the next event occurs, otherwise the previous captured sampling value will be lost.

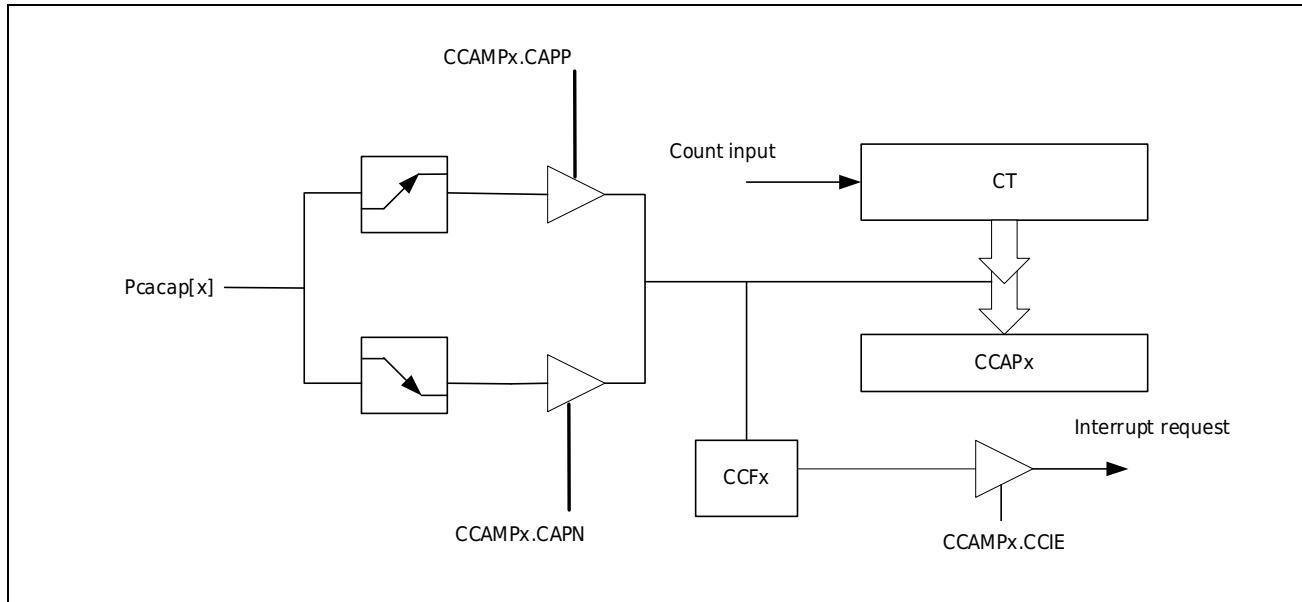

Figure 15-3 PCA Capture Functional Block Diagram

15.2.3 PCA comparison function

The comparison function provides the following functions, high-speed output mode, WDT mode, 16-bit PWM mode and 8-bit PWM mode. In the first three functions, the compare / capture module compares the value of the 16-bit PCA timer / counter with the 16-bit value preloaded into the module's CCAPx register. In 8-bit PWM mode, the PCA module continuously compares the PCA Timer / Counter Low Register (CNT) with an 8-bit value in the CCAPxL module register. The comparison is done every 4 clock cycles, which matches the clock rate of the fastest PCA timer/counter.

Setting the CCAPMx.ECOM bit selects the compare function for this module.

To use modules in compare mode correctly, follow the general procedure below:

- Select the operating mode of the PCA module.
- Selects the input signal for the PCA timer / counter.
- The compare value is loaded into the module's compare / capture register pair.
- Set the PCA timer / counter run control bit.
- An interrupt is generated after a match, and the compare/capture flag of the module is cleared.

15.2.3.1 Compare Toggle Output Mode

In the compare toggle output mode, whenever the value in the PCA counter matches the 16-bit capture / compare register (CCAPx) of the module, the logic level on the CH[x] pin of the module PCA will change. higher precision than switching IO output, because this output will not be interrupted to respond and affect the output frequency. If the CPU is used to switch the IO output, power consumption and precision are lacking.

To set the compare toggle output mode of a compare / capture module, set the CCAPMx.ECOM, CCAPMx.MAT and CCAPMx.TOG bits. PCA timer / counter and the compare / capture register (CCAPx) toggles the PCA 's CH[x] signal and sets the module's compare / capture flag (CCON.CCFx). By software setting or clearing the CH[x] signal of the PCA, the user can choose to match the switching signal from low to high or high to low.

The user can also choose to generate an interrupt request, by setting the corresponding interrupt enable bit (CCAPMx.CCIE), when a match occurs, an interrupt request can be generated. Since the compare/capture flag interrupt cannot be cleared by hardware, the user must clear this flag in software. If the user does not change the comparison/capture register in the interrupt program, PCA will re-count the comparison value, and if it matches, the next rollover will occur. In the interrupt service routine, a new 16 -bit compare value can be written to the compare / capture register (CCAPx).

Note:

- To prevent invalid matches while updating these registers, user software should write CCAPxL first and then CCAPxH. Writing to CCAPxL clears the ECOM bit which disables the compare function, while writing to CCAPxH sets the ECOM bit and re-enables the compare function.

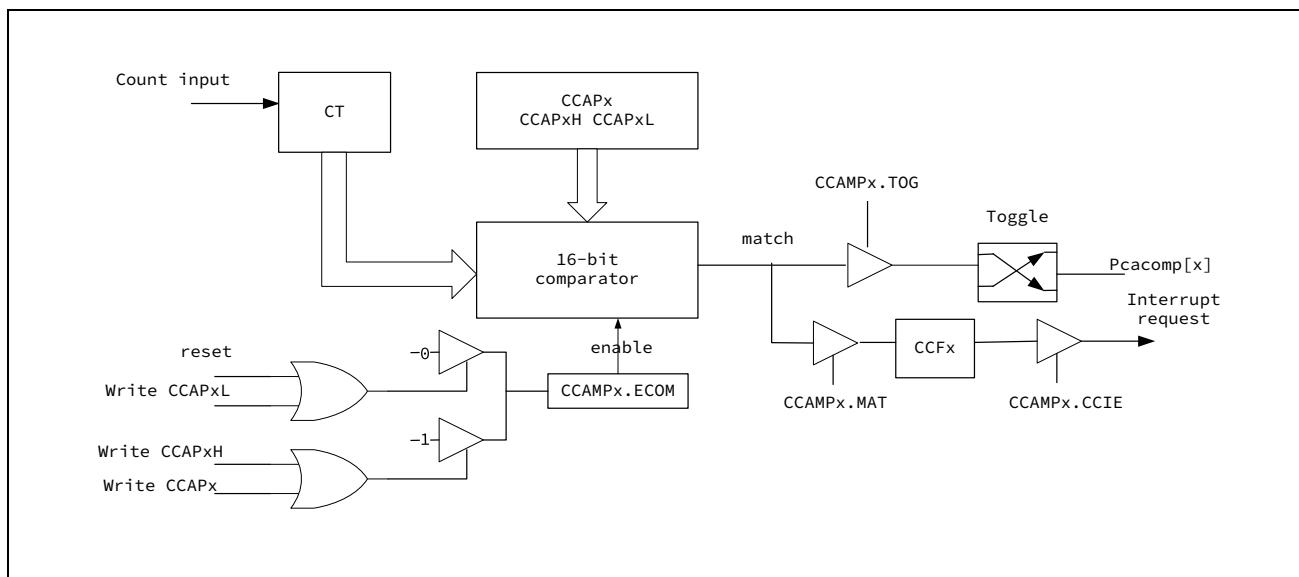

Figure 15-4 PCA Comparison Functional Block Diagram

15.2.3.2 PCA 16 -bit PWM function

In compare output PWM mode, whenever the value in the PCA counter matches the 16 -bit capture / compare register (CCAPx) of the module, the logic level on the CH[x] pin of the module PCA will change. When the counter overflows, the logic level on the CH[x] pin will be cleared. This can provide a set of 16 -bit PWM outputs.

To set the PWM mode of a compare / capture module, set the CCAPMx.ECOM, CCAPMx.MAT and CCAPMx.TOG bits and the EPWM register. PCA timer / counter and the compare / capture register (CCAPx) toggles the PCA 's CH[x] signal and sets the module's compare / capture flag (CCON.CCFx).

The user can also choose to generate an interrupt request, by setting the corresponding interrupt enable bit (CCAPMx.CCIE), when a match occurs, an interrupt request can be generated. Since the compare/capture flag interrupt cannot be cleared by hardware, the user must clear this flag in software.

Note: When using 16-bit PWM, it is recommended not to use the frequency division of PCA, otherwise the duty ratio output will differ by a maximum of one cycle.

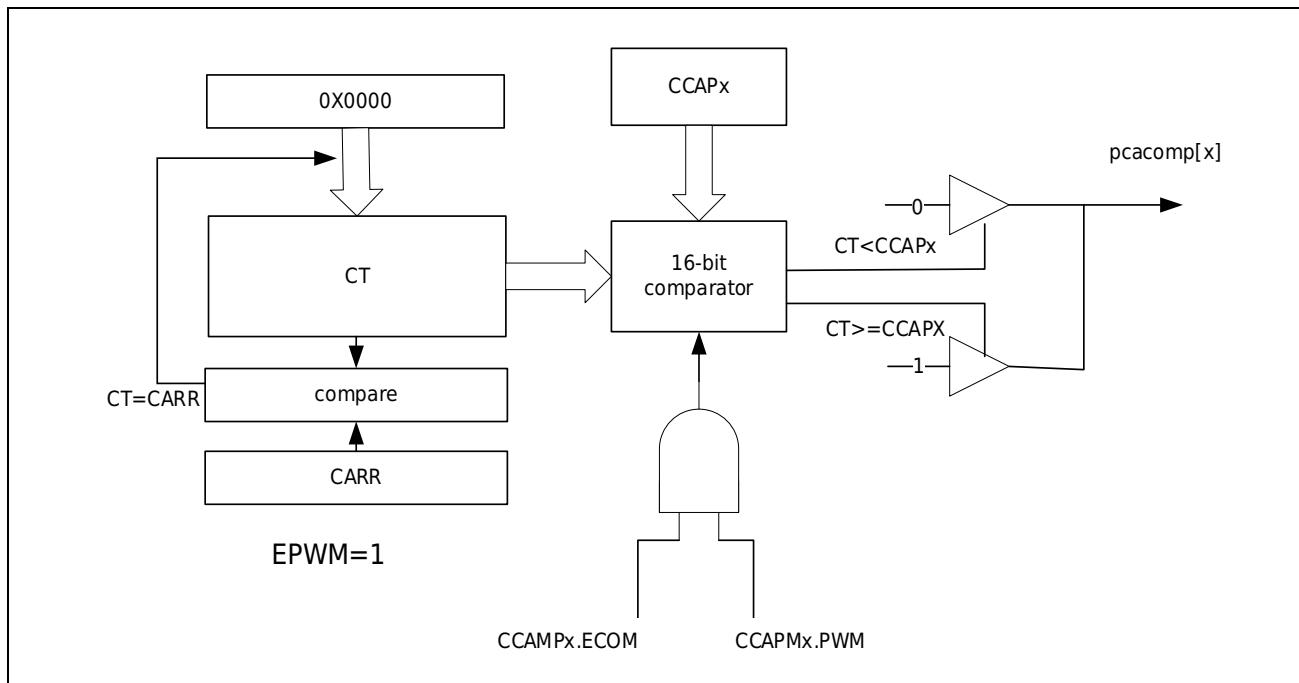

Figure 15-5 PCA 16-bit PWM functional block diagram

15.2.3.3 WDT function of PCA module 4

WDT hardware module, PCA module 4, this series also provides a 16-bit WDT with programmable frequency. This mode generates a reset signal when the count value of the PCA timer/counter matches the value compare/capture register (CCAP4) stored in module 4. WDT reset signal of PCA is used as an independent reset signal. Combined with external reset (RST), hardware watchdog reset (WDTRST) and LVD low voltage reset, POR power-on and power-off reset. Users are free to combine them or use them individually. Module 4 is the one with the unique PCA of the WDT pattern. When not set as WDT, it can be used independently in other modes.

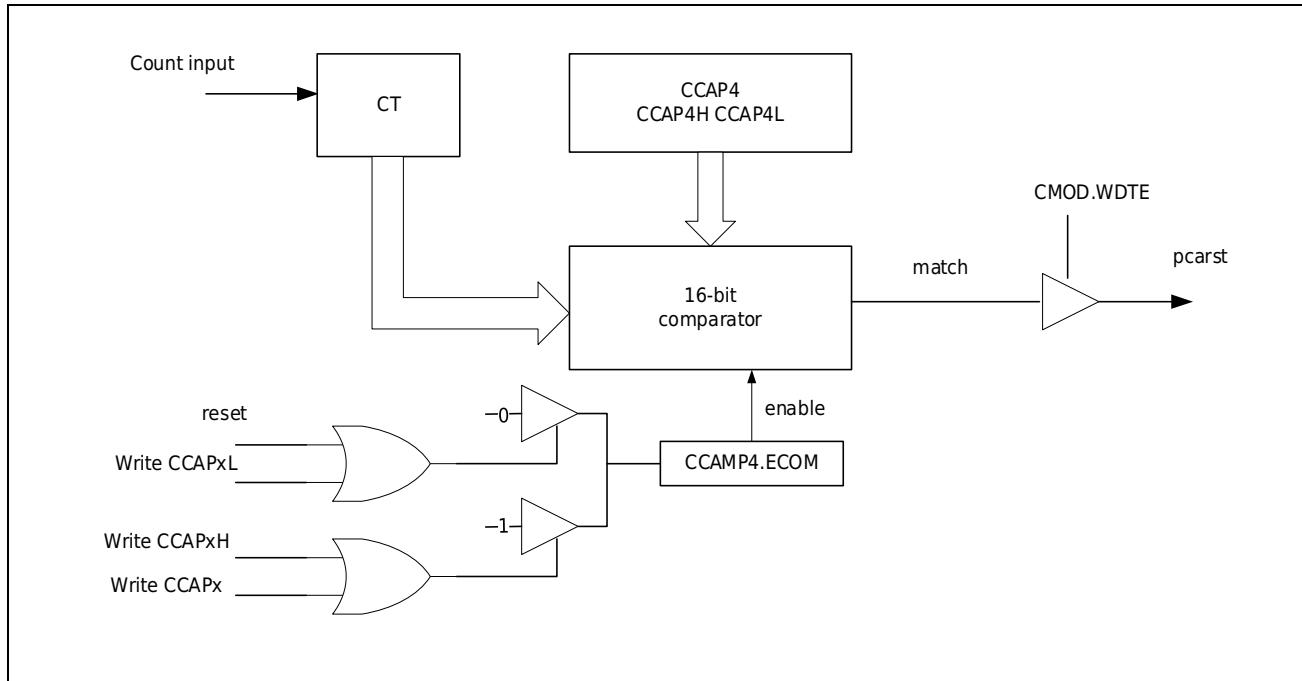

Figure 15-6 PCA WDT Functional Block Diagram

When PCA module 4 is used as WDT, CCAPM4.ECOM4, CCAPM4.MAT4 and CMOD.WDTE must be set. In addition, the PCA timer / counter can set CMOD.CPS to select different input counting frequencies.

Input a 16 -bit compare value in the compare / capture register (CCAP4). In the PCA timer / counter (CNT), enter a 16 -bit initial value or use a reset value (0000h). these values multiplied by the PCA input pulse rate determines the WDT match run time. Setting the Timer / Counter Run Control bit (CCON.CR) starts the PCA WDT. The WDT of the PCA generates a reset signal every time there is a match. To prevent a PCA WDT from resetting, the user has three options.

- Periodically the comparison value CCAP4 changes, so a match never occurs.
- Periodically change the PCA timer / counter value (CNT) so a match never happens.
- CMOD.WDTE bit before a match, and re-enable it later.

The first two options are more reliable because the WDT is not disabled in the third option.

The second option is not recommended if other PCA modules are used, since the five modules share a common time base. Therefore, the first option is best in most applications.

PCA WDT configuration process

- 1) Configure WDT compare / capture register PCA_CCAP4
- 2) Configure the PCA count register PCA_CNT
- 3) Configure PCA_CCAMP4 to select the compare and match function
- 4) Configure PCA_CMOD to select the input clock and enable the WDT function
- 5) Start PCA
- 6) Select clear PCA WDT clear mode to clear PCA WDT before PCA WDT reset

15.2.3.4 PCA 8-bit PWM function

Pulse Width Modulation is a technique that uses a program to control the duty cycle, period, and phase of a waveform. Each of the five PCA modules can be used independently to generate a pulse width modulation (PWM) output on the corresponding PCA's CH[x] pin, with a pulse width of 8-bit resolution. The frequency of the PWM output depends on the time base of the PCA counter/timer. Use the capture / compare register CCAPxL of the module to change the duty cycle of the PWM output signal. When the low byte (CL) of the PCA counter / timer is equal to the value in CCAPxL, the output on the CH[x] pin of the PCA is set to "1"; when the count value in CL overflows, the CH [x] pin of the PCA [x] Output is reset to "0". When the low byte CL of the counter / timer overflows (from 0xFF to 0x00), the value stored in CCAPxH is automatically loaded into CCAPxL without software intervention.

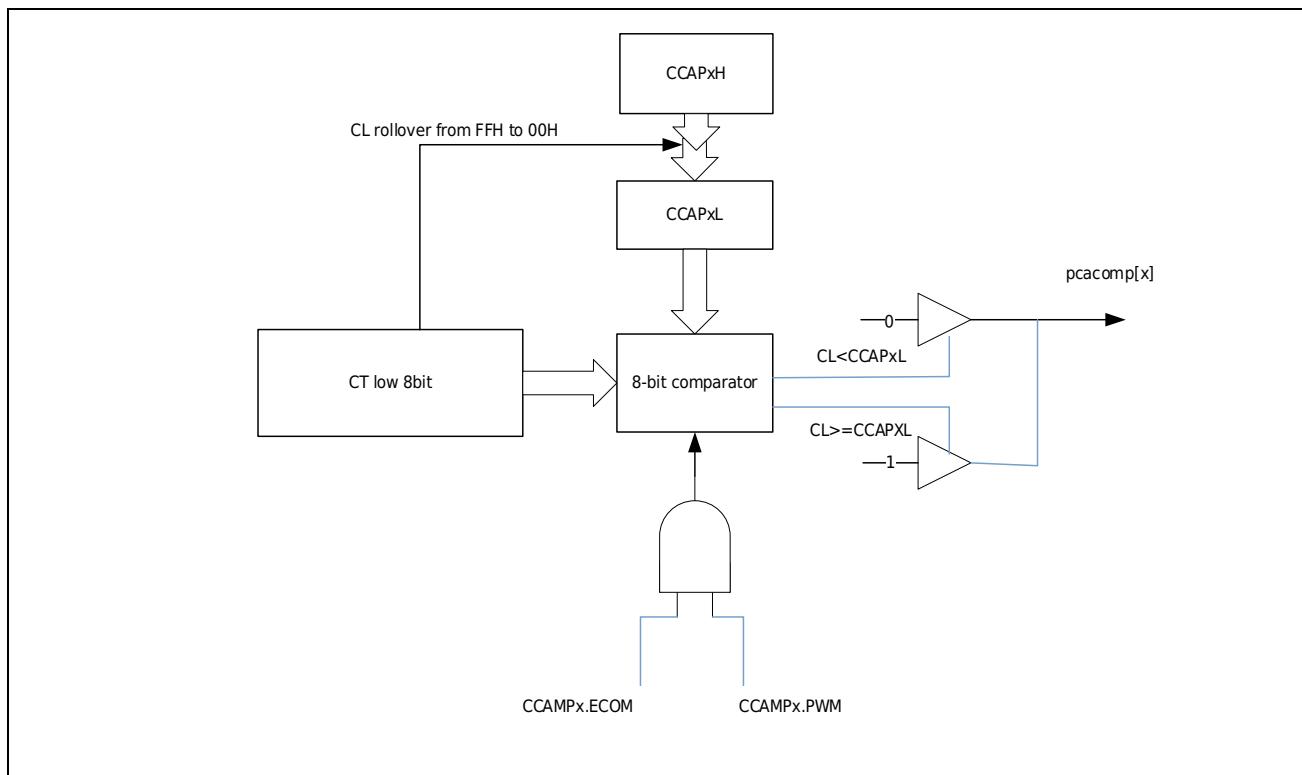

Figure 15-7 PCA PWM Functional Block Diagram

In this mode, the value in the low byte of the PCA timer / counter (CL) is constantly compared with the value in the low byte compare / capture register (CCAPxL). When $CL < CCAPxL$, the output waveform is low. When both match ($CL = CCAPxL$), the output waveform goes high until CL overflows from FFH to 00H, and remains high during the end period. On overflow, the value in CCAPxH is automatically loaded into CCAPxL, and a new cycle begins.

The value in CCAPxL determines the duty cycle of the current waveform. The value in CCAPxH determines the duty cycle of the next waveform Pulse Width Modulation that can be changed by changing the value in CCAPxL. As shown, the 8-bit value in CCAPxL can range from 0 (100 % duty cycle), to 255 (0.4 % duty cycle). To change the CCAPxL value without glitching, write a new value

in the high byte register (CCAPxH). When CL rolls over FFH to 00h, this value is automatically loaded into CCAPxL by hardware.

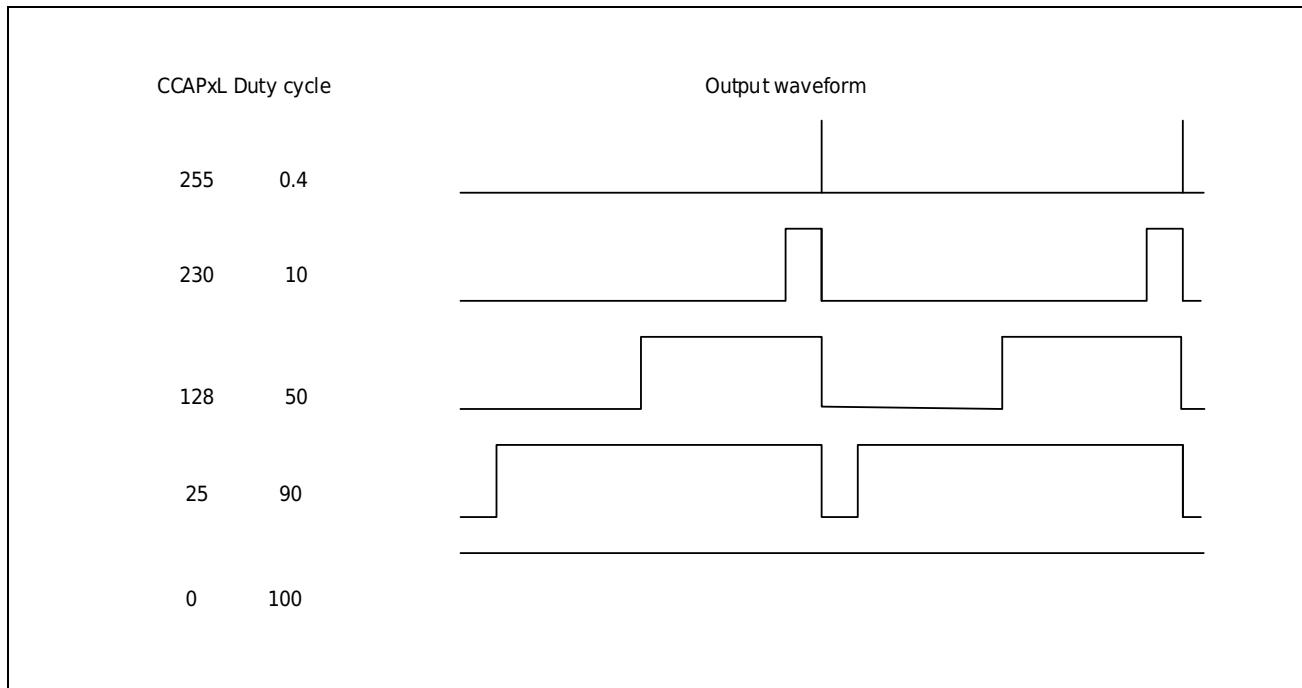

Figure 15-8 PCA PWM Output Waveform

To set a compare / capture module in PWM mode, the CCAPMx.ECOM and CCAPMx.PWM bits need to be set. In addition, the PCA timer / counter can select the input count signal frequency by programming CMOD.CSP[2:0]. Enter an 8 -bit value in CCAPxL to specify the duty cycle of the first PWM waveform. Entering an 8 -bit value in CCAPxH specifies the duty cycle of the second PWM waveform. Set the timer / counter run control bit (CCON.CR) to start the PCA timer / counter.

Table 15-1 PCA comparison capture function module setup

ECOM	CAPP	CAPN	MAT	TOG	PWM	ECCF	EPWM	Way of working
X	1	0	0	0	0	X	0	Capture with positive edge trigger
X	0	1	0	0	0	X	0	Trigger capture with negative edge
X	1	1	0	0	0	X	0	Capture with edge trigger
1	0	0	1	0	0	X	0	Software timer
1	0	0	1	1	0	X	0	High speed output
1	0	0	0	0	1	X	0	8 -bit pulse width modulator
1	0	0	1	1	0	X	1	16 -bit pulse width modulator

15.3 Interconnection and control of PCA module and other modules

PCA can be connected to other modules or ports through port function selection.

		0	1	2	3	4	5	6	7
GPIO_PCAS[2:0]	PCA_ECI	PX_SEL	Reserved	LVD	VC0	VC1	PA05	PB02	PD02
GPIO_PCAS[5:3]	PCA_CH0	PX_SEL	Reserved	Reserved	LVD	VC1	PA06	PB04	PC06

When GPIO_PCAS[2:0]=0x0, the PCA_ECI input is the port input selected by PX_SEL. When GPIO_PCAS[2:0]=0x1~0X7, it is connected to the input or output of other modules.

When GPIO_PCAS[5:3]=0x0, the PCA_CH0 capture input is the port input selected by PX_SEL. When GPIO_PCAS[5:3]=0x1~0X7, it is connected to the input or output of other modules.

16 Advanced Timer (TIM4/5/6)

16.1 Introduction to Advanced Timer

Advanced Timer is a Timer4/5/6 that contains three timers. Timer4/5/6 are high-performance counters with the same function, which can be used to count and generate different forms of clock waveforms. One timer can generate a complementary pair of PWM or independent 2-way PWM output, which can capture external input for pulse width or period Measurement.

The basic functions and features of Advanced Timer are shown in the table.

Table 16-1 Basic Features of Advanced Timer

Waveform mode	Sawtooth wave, triangular wave
Basic functions	• Direction of increments and decrements
	• Software synchronization
	• Hardware synchronization
	• Cache function
	• Orthogonal coding count
	• General purpose PWM output
	• Protection mechanism
	• AOS associated action
Interrupt type	Count comparison match interrupt
	Count cycle match interrupt
	Dead time error interrupt

Table 16-2 Advanced Timer port list

Port name	Direction	Function
TIMx_CHA	Input/Output	Quadrature encoding count clock input port or capture input port or comparison output port (x=4~6)
TIMx_CHB		2) Hardware start, stop, clear condition input port
TIMTRIA	Input	
TIMTRIB		Hardware count clock input port or capture input port
TIMTRIC		Hardware start, stop, clear condition input port
TIMTRID		

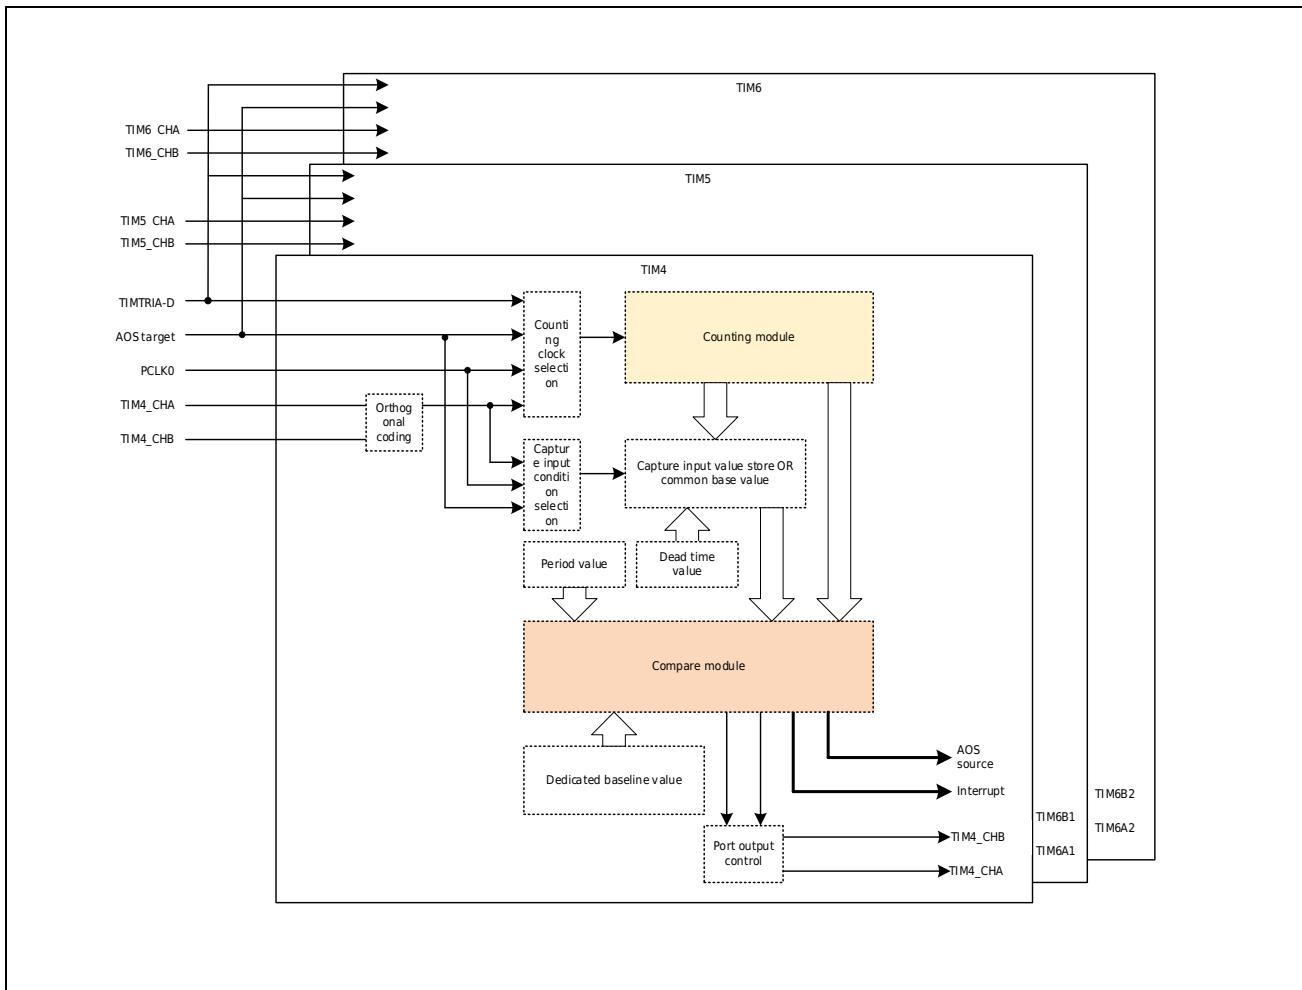

Figure 16-1 Advanced Timer Block Diagram

16.2 Advanced Timer Function Description

16.2.1 Basic action

16.2.1.1 Basic Waveform Mode

Timer4/5/6 has 2 basic counting waveform modes, sawtooth wave mode and triangle wave mode. The waveform mode is subdivided due to different internal counting actions. The triangular wave mode is divided into triangular wave A mode and triangular wave B mode. The basic waveforms of sawtooth and triangle waves are shown in Figure 16-2 and Figure 16-3. The difference between the triangular wave A mode and the triangular wave B mode is that there is a difference in the buffer transfer. The triangular wave A mode only has one buffer transfer (valley point) in one cycle, while the triangular wave B mode has two buffer transfers (peak point and valley point) in one cycle.

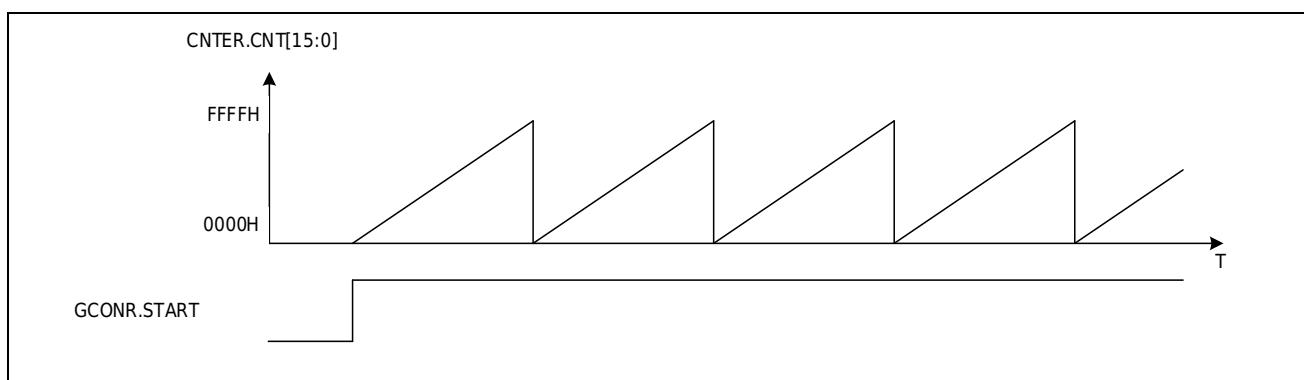

Figure 16-2 Sawtooth Waveform (Counting Up)

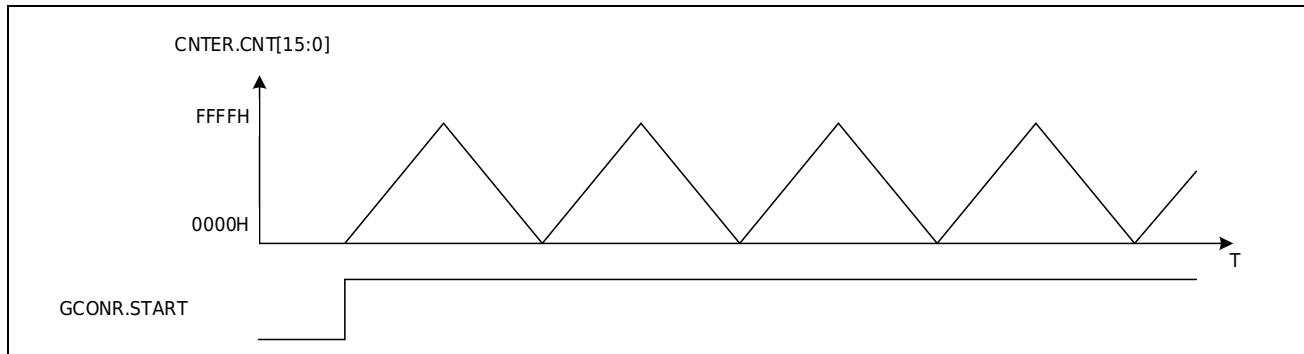

Figure 16-3 Triangle Waveform

16.2.1.2 Comparison output

Timer4/5/6 A timer has 2 comparison output ports (CHxA, CHxB), which can output a specified level when the count value matches the count reference value. The GCMAR and GCMBR registers correspond to the count comparison reference values of CHxA and CHxB respectively. When the count value of the counter is equal to GCMAR, the CHxA port outputs the specified level; when the count value of the counter is equal to GCMBR, the CHxB port outputs the specified level.

The counting start level, stop level, and counting comparison match level of CHxA and CHxB ports can be set by PCONR.STACA, PCONR.STPCA, PCONR.STASTPSA, PCONR.CMPCA [1:0] of the port control register (PCONR), PCONR.PERCA[1:0] and PCONR.STACB, PCONR.STPCB, PCONR.STASTPSB, PCONR.CMPCB[1:0], PCONR.PERCB[1:0] bit settings. Figure 16-4 is an example of the comparison output operation.

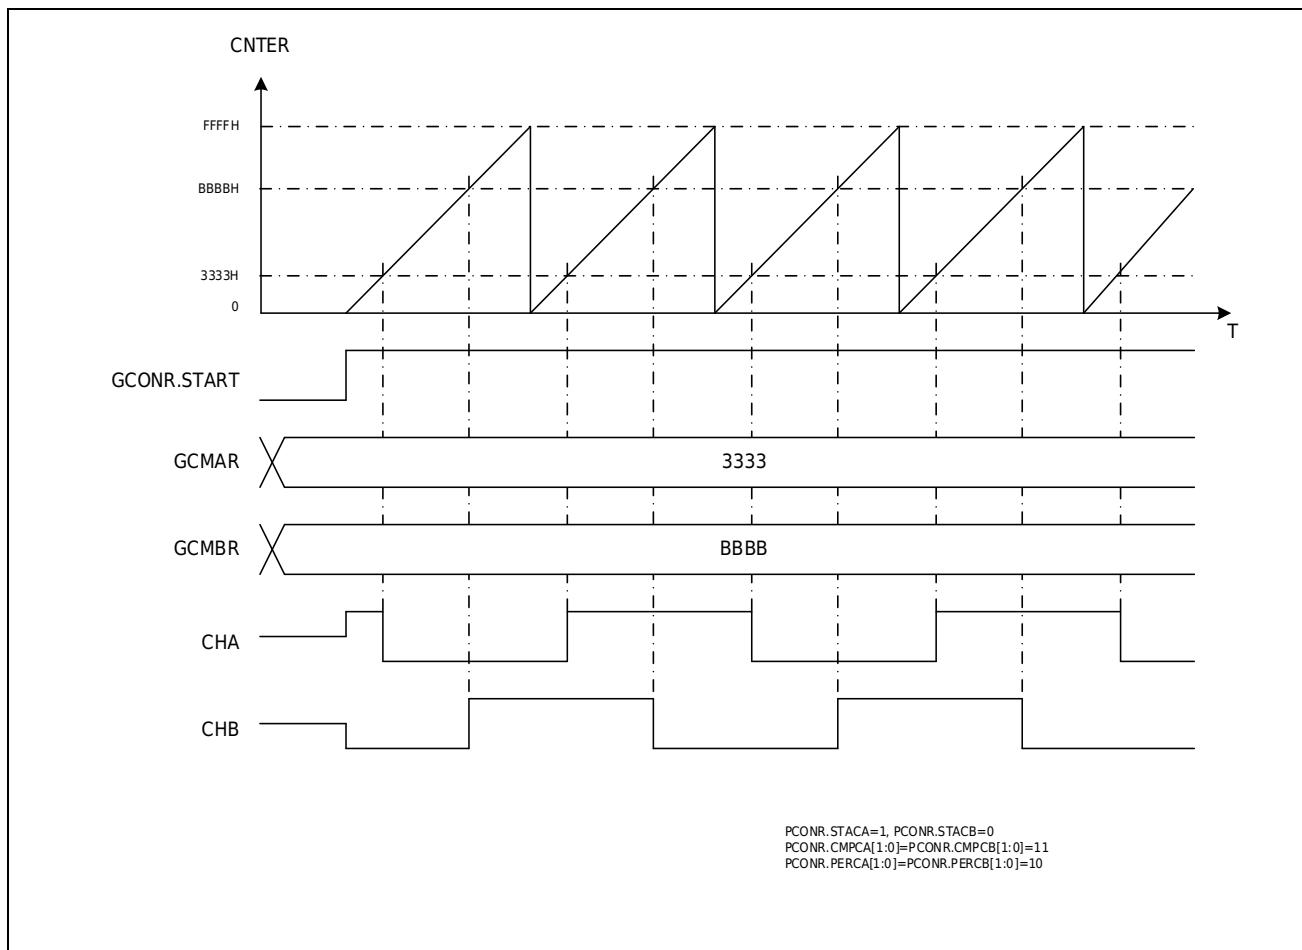

Figure 16-4 Compare output action

16.2.1.3 Capture input

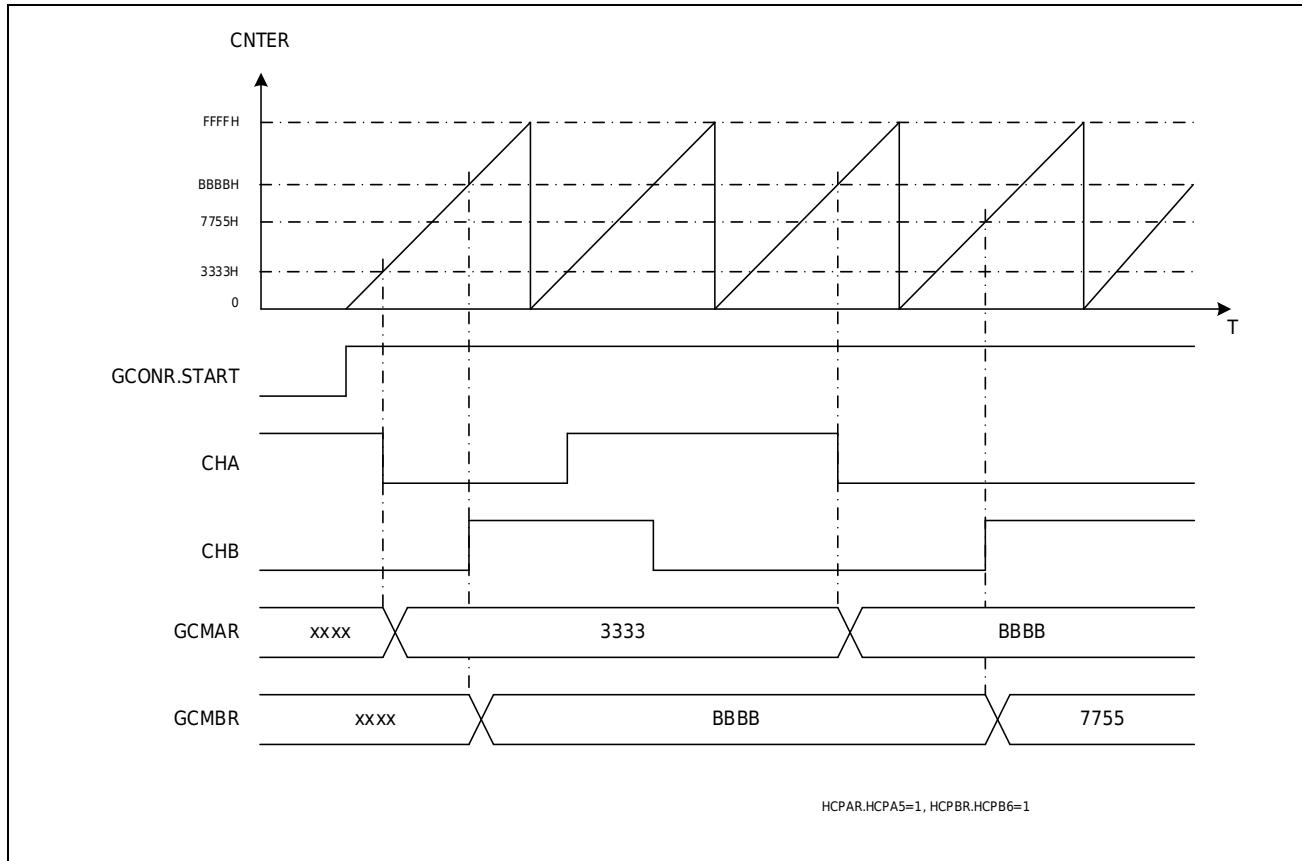

Figure 16-5 Capturing Input Actions

Timer4/5/6 all have a capture input function, with 2 sets of capture input registers (GCMAR, GCMBR), used to save the captured count value. Set the PCONR.CAPCA and PCONR.CAPCB bits of the port control register (PCONR) to 1, and the capture input function is valid. When the corresponding capture input condition is set and the condition is valid, the current count value is saved to the corresponding register (GCMAR, GCMBR).

The condition of each capture input can be AOS event trigger, TIMTRIA-TIMTRID input, CHxA or CHxB input, etc. The specific condition selection can be set through the hardware capture event selection register (HCPAR, HCPBR). Figure 16-5 is an example of an action to capture input.

16.2.2 Timer selection

Timer4/5/6 can have the following options:

- PCLK and 2, 4, 8, 16, 64, 256, 1024 frequency division of PCLK (GCONR.CKDIV[2:0] setting)
- AOS event trigger input (set by HCUPR.HCUP[19:16] or HCDOR.HCDO[19:16])
- CHxA and CHxB (set by HCUPR.HCUP[7:0] or HCDOR.HCDO[7:0])
- TIMTRIA-TIMTRID (HCUPR.HCUP [15:8] or HCDOR.HCDO [15:8] setting)

It can be seen from the above description that clocks b, c, and d are independent of each other, and can be set to be valid or invalid respectively, and when clocks b, c, and d are selected, clock a is automatically invalid.

16.2.3 Counting direction

Timer4/5/6 can be changed by software. The method of changing the counting direction is slightly different in different waveform modes.

16.2.3.1 Sawtooth counting direction

In sawtooth wave mode, the counting direction can be set while the counter is counting or stopped.

When counting up, set GCONR.DIR=0 (count down), then the counter will change to down count mode after counting to overflow; when counting down, set GCONR.DIR=1 (count up), the counter will change to count up mode after counting to underflow.

When counting is stopped, the GCONR.DIR bit is set. GCONR.DIR will not be reflected in the counting until the counting starts until overflow or underflow.

16.2.3.2 Triangular wave counting direction

In triangle wave mode, the counting direction can only be set when the counter is stopped. It is invalid to set the counting direction in counting.

When counting is stopped, the GCONR.DIR bit is set. GCONR.DIR will not be reflected in the counting until the counting starts until overflow or underflow.

16.2.4 Digital filtering

The CHxA, CHxB, TIMTRIA~D port inputs of Timer4/5/6 all have digital filter function. The filter function of the corresponding port can be enabled by setting the relevant enable bit of the filter control register (FCONR). The reference clock used for filtering is also set by the filter control register (FCONR).

When the filtered sampling reference clock is sampled to the same level three times on the port, the level is transferred to the module as an effective level. A level less than three times consistent will be filtered out as external interference and not transmitted to the module. Its operation is shown in Figure 16-6, for example.

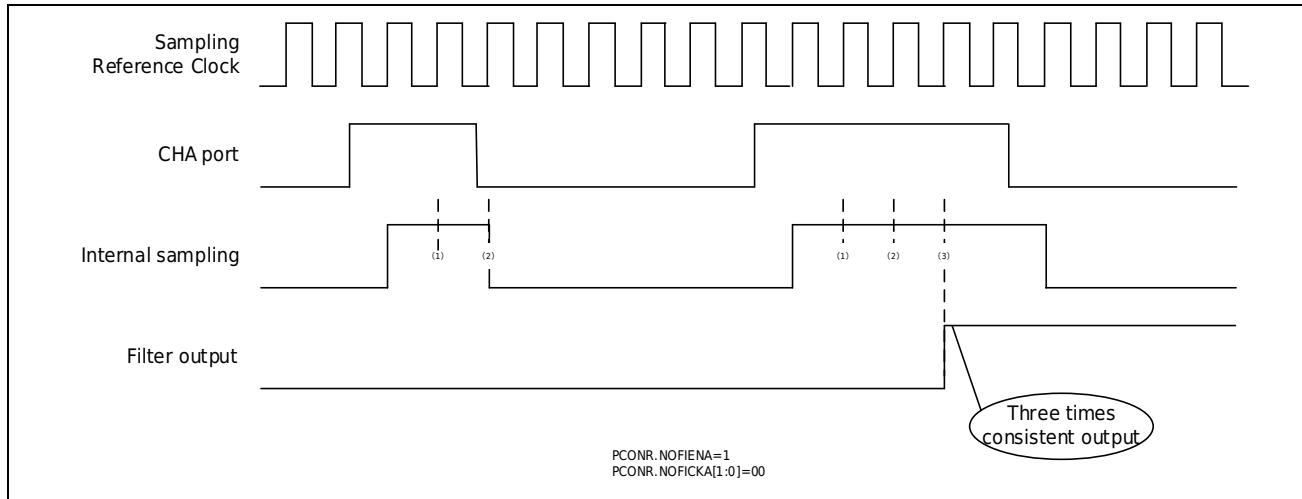

Figure 16-6 Filter function of the capture input port

TIMTRIA~D ports are a group of ports shared by Timer4/5/6. The digital filtering function of this group of ports is only implemented on Timer4, and the digital filtering function of other timers Timer5/6 is invalid for this group of ports.

16.2.5 Software synchronization

16.2.5.1 Software synchronization start

Timer4/5/6 can realize the synchronous start of the target Timer4/5/6 by setting the relevant bits of the software synchronous start register (SSTAR).

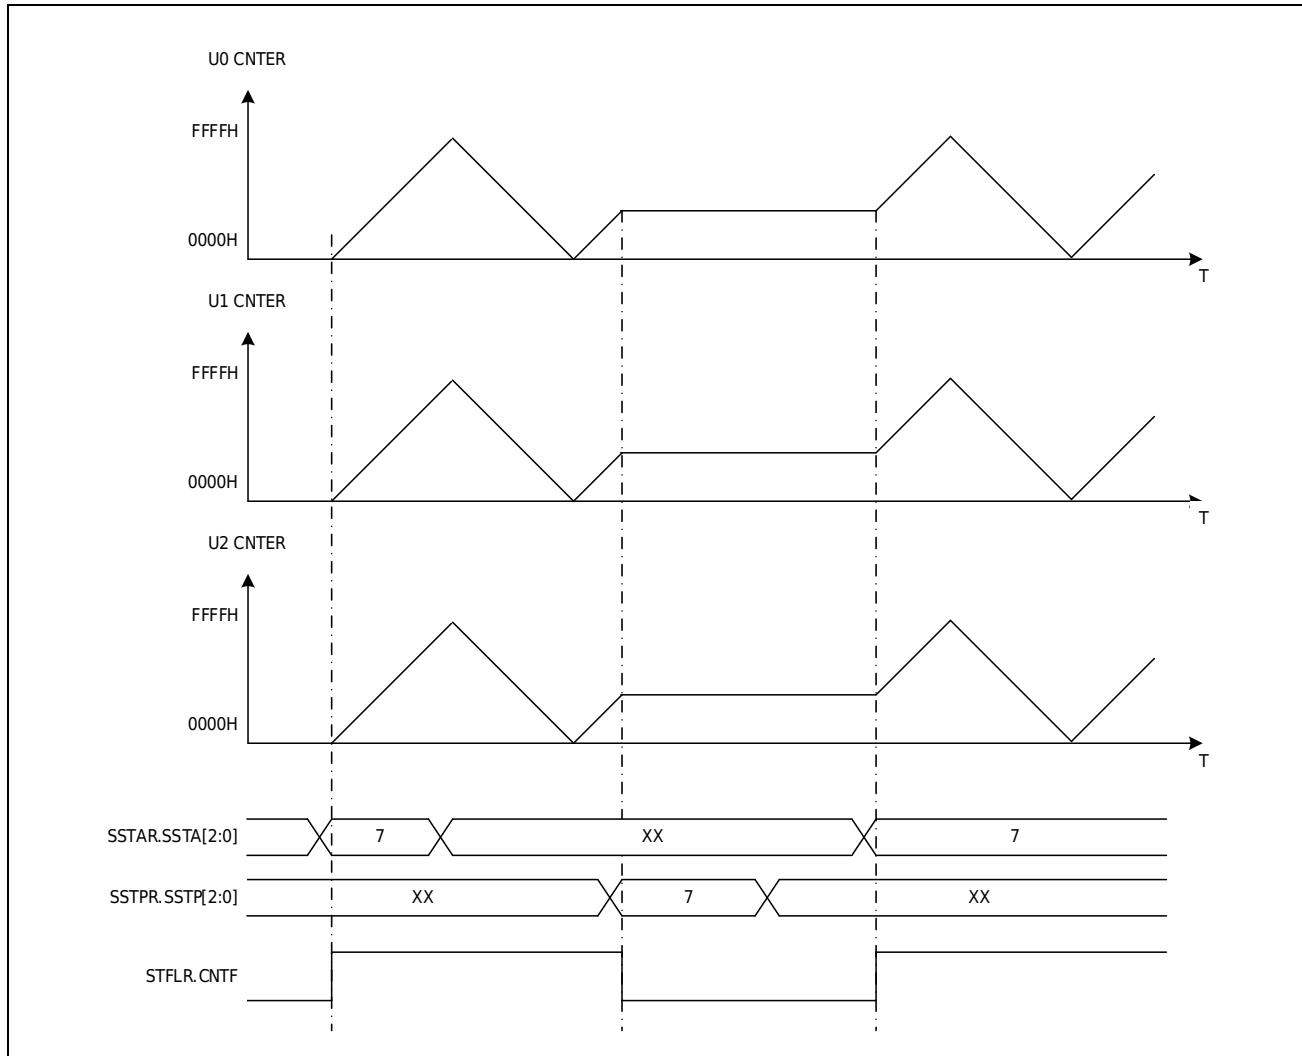

Figure 16-7 Software Synchronization Action

16.2.5.2 Software co-stop

Timer4/5/6 can realize the synchronous stop of the target Timer4/5/6 by setting the relevant bits of the software synchronous stop register (SSTPR).

16.2.5.3 Software synchronous clear

Timer4/5/6 can realize the synchronous clear of the target Timer4/5/6 by setting the relevant bits of the software synchronous clear register (SCLRR).

As shown in Figure 16-7, if SSTAR. SSTA0=SSTAR. SSTA1=SSTAR. SSTA2 is set for Timer4, software synchronization startup for Timer4/5/6 can be achieved.

Software synchronous action related registers (SSTAR, SSTPR, SCLRR) are a group of registers that are independent of Timer4/5/6 and shared between each TIM. Each bit of this group of registers is only valid when writing 1, and writing 0 is invalid. When reading the SSTAR register, the counter status of each timer will be read, and when reading SSTPR or SCLRR, 0 will be read.

16.2.6 Hardware synchronization

In addition to having 2 general-purpose input ports (CHxA, CHxB) independently, each timer also has 4 external general-purpose input ports (TIMTRIA, TIMTRIB, TIMTRIC, TIMTRID) and 4 AOS targets, which can realize the hardware between timers Synchronized actions.

16.2.6.1 Hardware sync start

Each Timer4/5/6 can choose to use hardware to start the counter, select the timer with the same hardware start condition to realize synchronous start when the start condition is valid. The specific hardware start condition is determined by the setting of the hardware start event selection register (HSTAR).

16.2.6.2 Hardware co-stop

Each Timer4/5/6 can choose to stop the counter by hardware, and the timer with the same hardware stop condition can realize synchronous stop when the stop condition is valid. The specific hardware stop condition is determined by the setting of the hardware stop event selection register (HSTPR).

16.2.6.3 Hardware synchronous clear

Each Timer4/5/6 can choose to clear the counter by hardware, and select the timer with the same hardware clearing condition to realize synchronous clearing when the clearing condition is valid. The specific hardware clear condition is determined by the setting of the hardware clear event select register (HCLRR).

16.2.6.4 Hardware Synchronous Capture Input

Each Timer4/5/6 can choose to use hardware to realize the capture input function, and select the timer with the same capture input function condition to realize synchronous capture input when the capture input function condition is valid. The specific hardware capture input function conditions are determined by the settings of the hardware capture event selection registers (HCPAR, HCPBR).

16.2.6.5 Hardware sync count

Timer4/5/6 can choose to use the hardware input as CLOCK to count, and select the timer with the same hardware counting condition to realize synchronous counting when the hardware counting CLOCK is valid. The specific hardware counting conditions are determined by the settings of the hardware increment event selection register (HCUPR) and the hardware decrement event selection register (HCDOR).

When the hardware synchronous counting function is selected, only the external input clock source is selected, which does not affect the start, stop, and reset actions of the counter. The start, stop, and reset of the counter also need to be set separately.

Figure 16-8 shows an example of the hardware synchronous operation of Timer4/5/6.

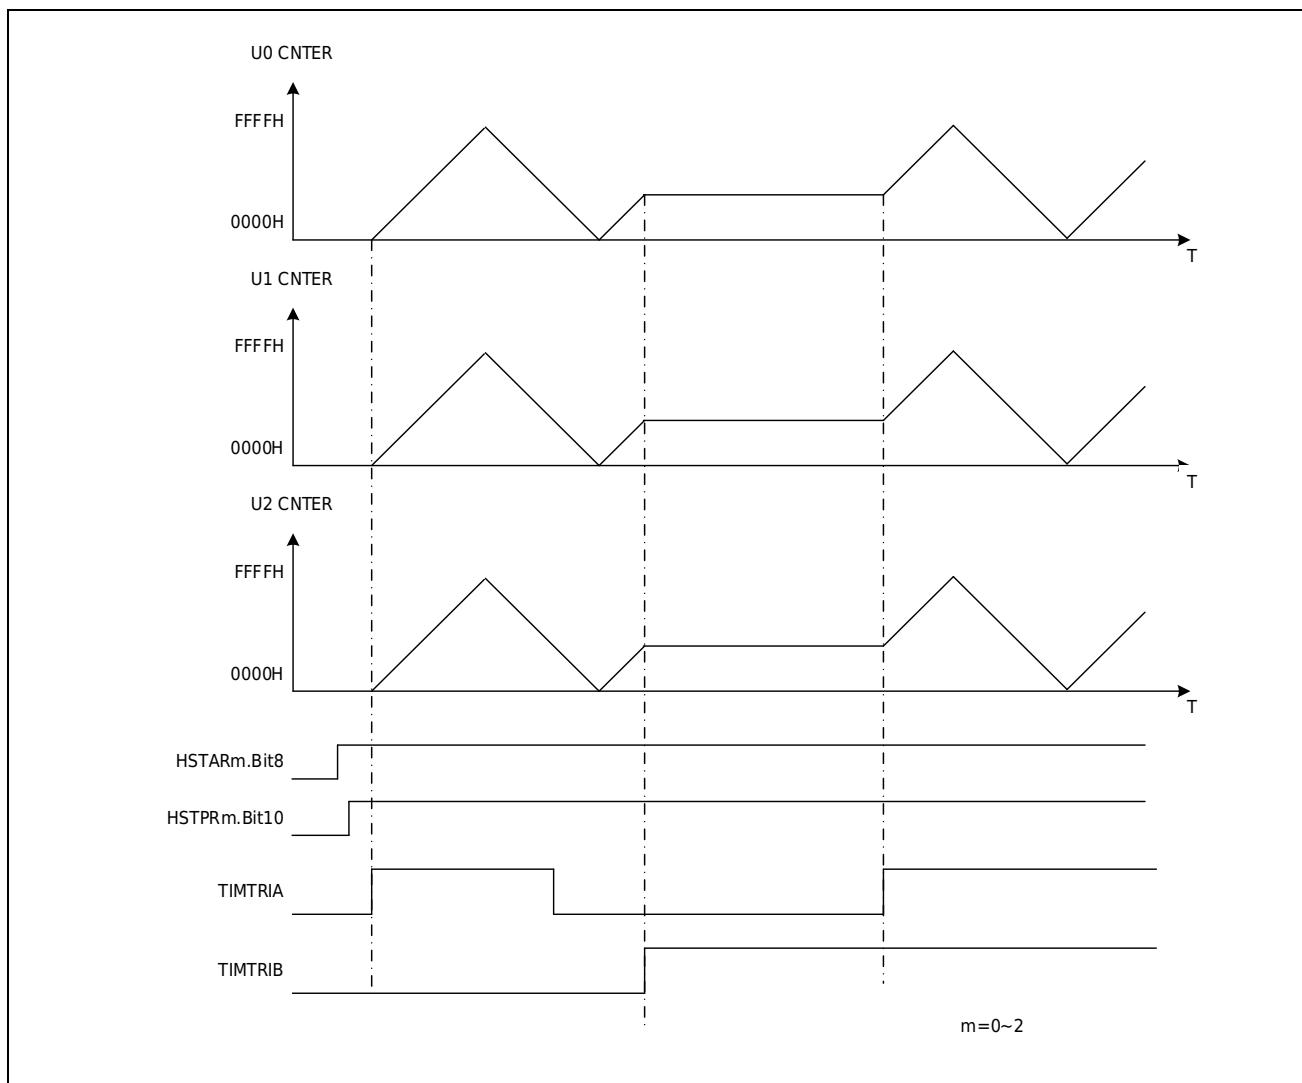

Figure 16-8 Hardware Synchronous Action

16.2.7 Cache function

Cache action means that by setting the cache control register (BCONR), at the time point of cache transmission, the following events are selected:

- The value of the general period reference buffer register (PERBR) is automatically transferred to the general period reference register (PERAR)
- The value of the general comparison reference value buffer register (GCMCR, GCMDR) is automatically transferred to the general comparison reference value register (GCMAR, GCMBR) (when comparing output)
- The value of the general comparison reference value register (GCMAR, GCMBR) is automatically transferred to the general comparison reference value buffer register (GCMCR, GCMDR) (when capturing input)

Figure 16-9 shows the timing chart of the single cache method of the universal comparison reference value register when comparing output actions. It can be seen from the figure that changing the value of the general comparison reference value register (GCMAR) during counting can adjust the output duty cycle, and changing the value of the general period reference value register (PERAR) can adjust the output cycle.

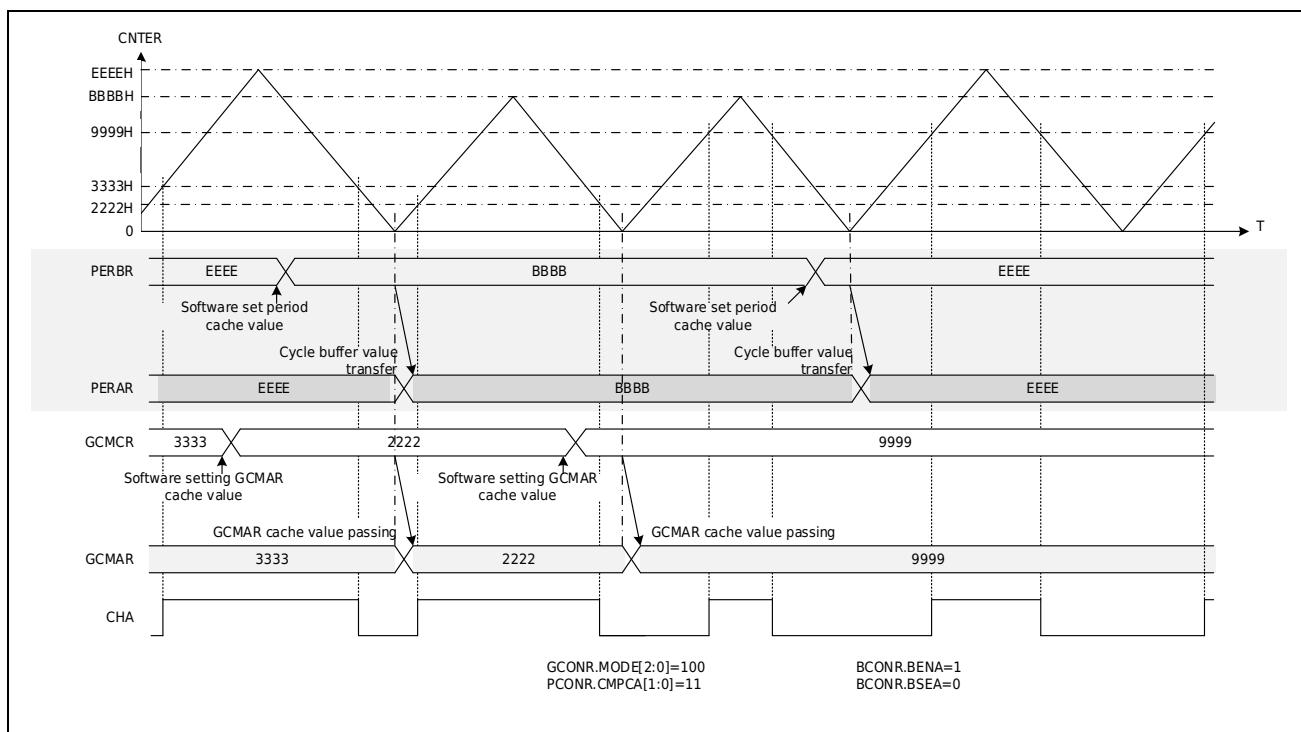

Figure 16-9 Single-buffer mode comparison output timing

16.2.7.1 Cache delivery time point

General cycle reference value cache transmission time point

The transmission time point of the periodic reference value buffer is the counting overflow point or the counting down point when the sawtooth wave occurs, and the counting valley point when the triangular wave occurs.

Universal baseline value cache delivery time point

In sawtooth wave mode, set BCONR.BENA=1 or BCONR.BNEB=1, and the cache operation is valid. Buffer transfers occur at overflow or underflow points.

In triangular wave A mode, set BCONR.BENA=1 or BCONR.BNEB=1, the cache operation is valid. Buffer transfers occur at count valley points.

In triangular wave B mode, set BCONR.BENA=1 or BCONR.BNEB=1, the cache operation is valid. Buffer transfers occur at count troughs and count peaks.

Capture input value buffer transfer time point

The capture input action cache transmission time point is when the capture input action is performed.

Buffer transfer during clear action

In the sawtooth wave counting mode or hardware counting mode, if there is a clearing action during the normal comparison output operation, the general cycle reference value, general comparison reference value, etc. will be buffered once according to the corresponding buffer operation setting status.

16.2.8 General PWM output

16.2.8.1 PWM spread spectrum output

In order to reduce the external interference of the PWM output, there is a spread spectrum configuration in the PWM output stage. Each PWM output cycle fine-tunes the phase of the PWM output.

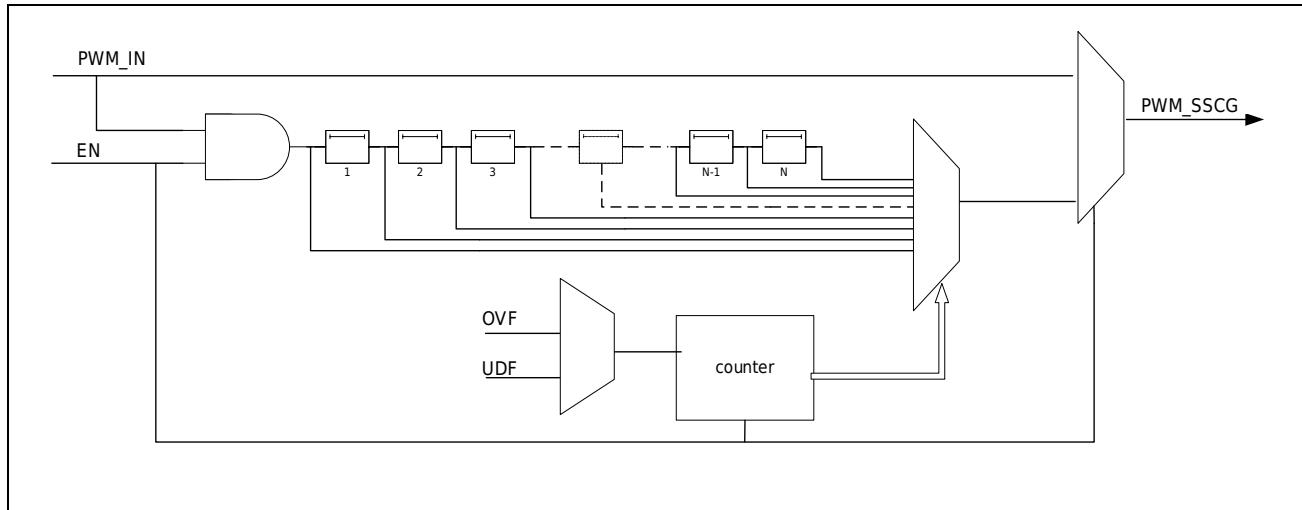

Figure 16-10 PWM Spread Spectrum Output Schematic

16.2.8.2 Independent PWM output

The 2 ports CHxA and CHxB of each timer can independently output PWM waves. As shown in Figure 16-11, the CHA port of Timer6 outputs PWM wave.

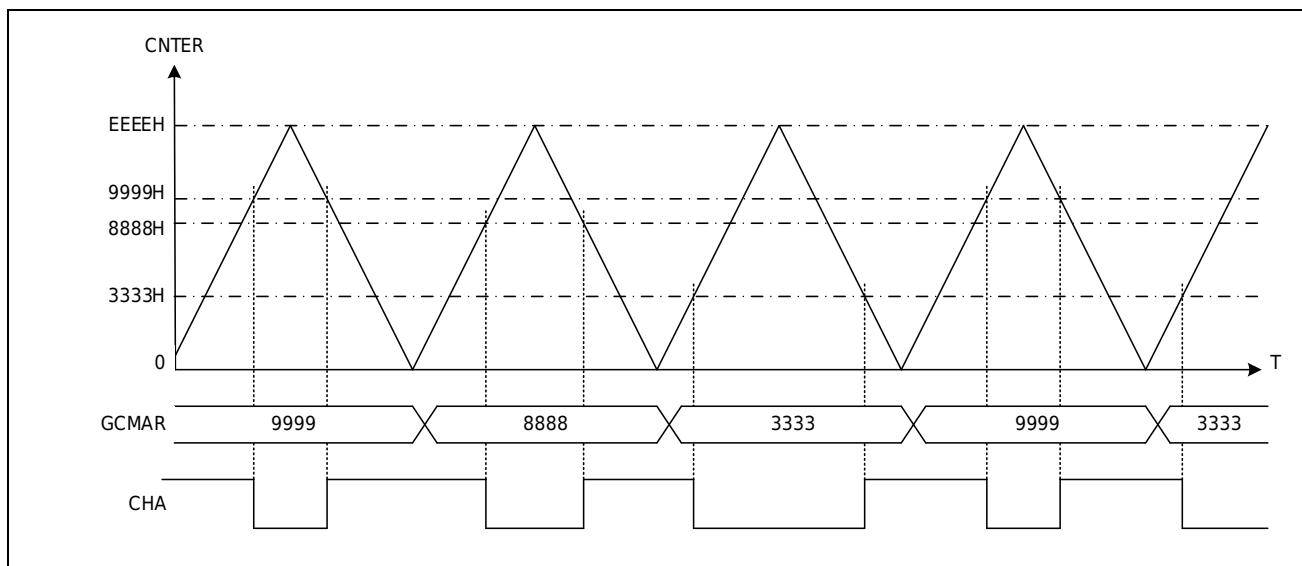

Figure 16-11 CHA output PWM wave

16.2.8.3 Complementary PWM output

The CHxA port and the CHxB port can be combined to output complementary PWM waveforms in different modes.

Software setting GCMBR complementary PWM output

Software setting GCMBR complementary PWM output means that in sawtooth wave mode, triangular wave A mode, and triangular wave B mode, the value of the general comparison reference value register (GCMBR) used for CHxB port waveform output is directly set by the register, and the general comparison reference The value of the value register (GCMAR) is not directly related.

Figure 16-12 shows an example of software setting GCMBR complementary PWM wave output.

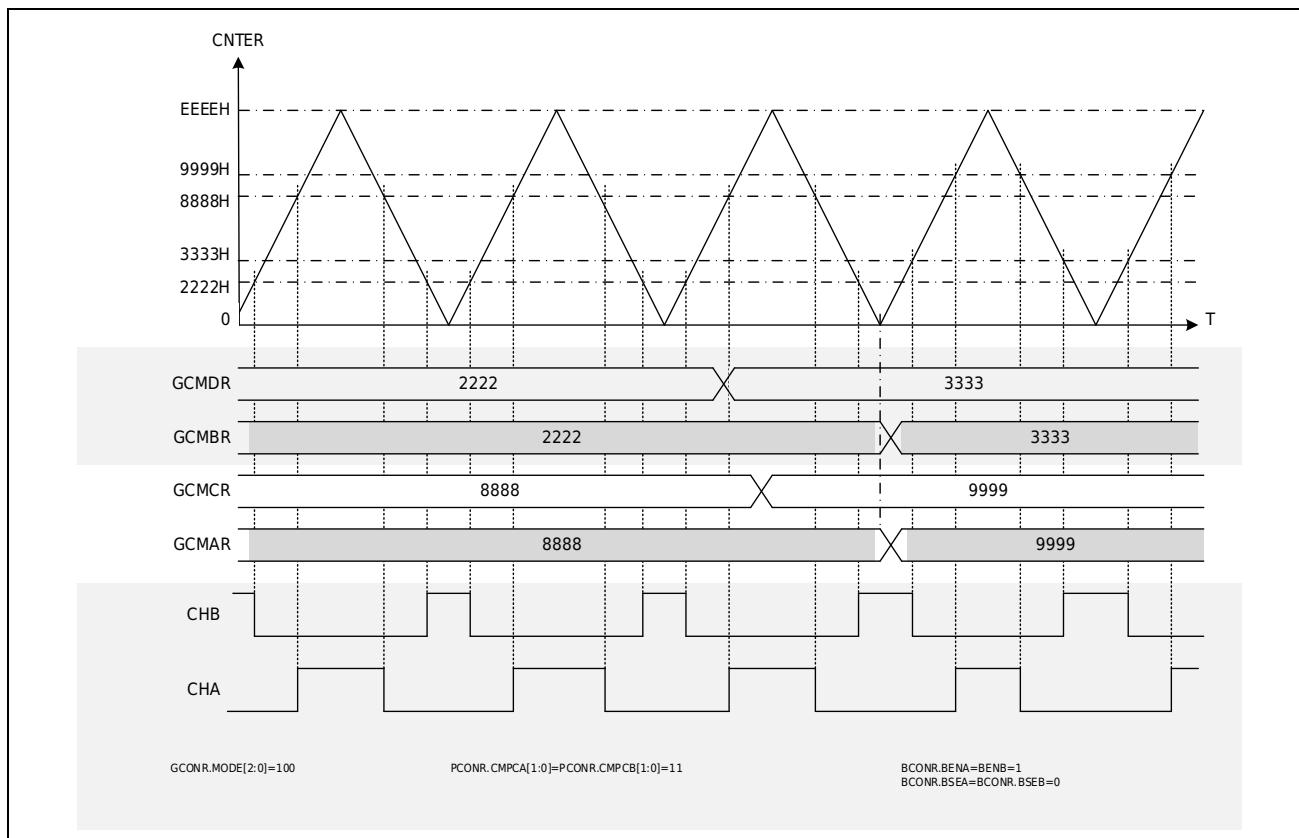

Figure 16-12 Software setting GCMBR Complementary PWM wave output in triangular wave A mode

Hardware setting GCMBR complementary PWM output

Hardware setting GCMBR Complementary PWM output means that in triangular wave A mode and triangular wave B mode, the value of the general comparison reference value register (GCMBR) used for CHxB port waveform output is determined by the general comparison reference value register (GCMAR) and the dead time reference The value operation of the value register (DTUAR, DTDAR) is determined.

Figure 16-13 is an example of hardware setting GCMBR complementary PWM wave output.

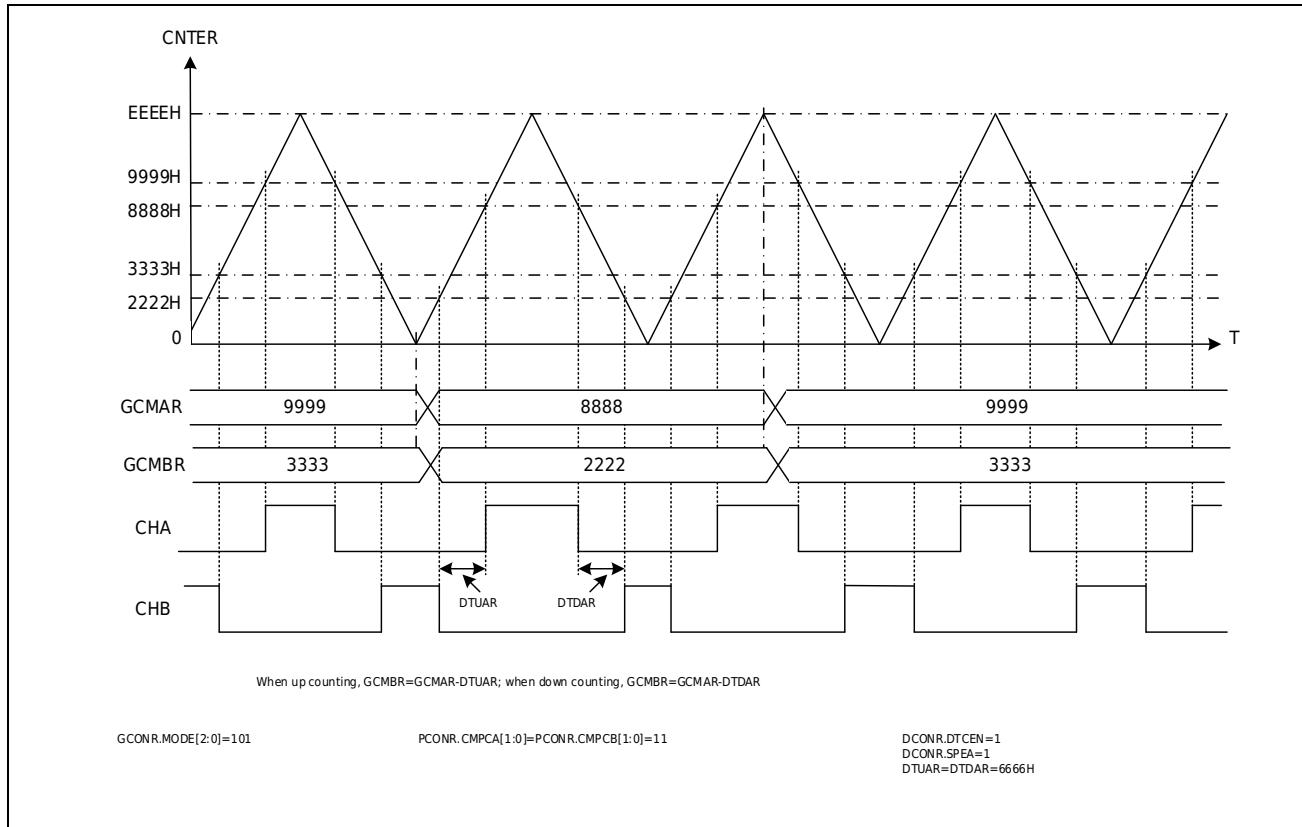

Figure 16-13 Triangular wave B mode hardware setting GCMBR Complementary PWM wave output (symmetrical dead zone)

16.2.8.4 Multi-phase PWM output

The CHxA and CHxB ports of each timer can output 2 -phase independent PWM waves or a group of complementary PWM waves. Multiple timers can be combined and combined with software and hardware synchronous actions to realize multi-phase PWM wave output. As shown in Figure 16-14, the combination of Timer4, Timer5, and Timer6 outputs 6-phase PWM waves; as shown in Figure 16-15, the combination of Timer4, Timer5, and Timer6 outputs 3 complementary PWM waves.

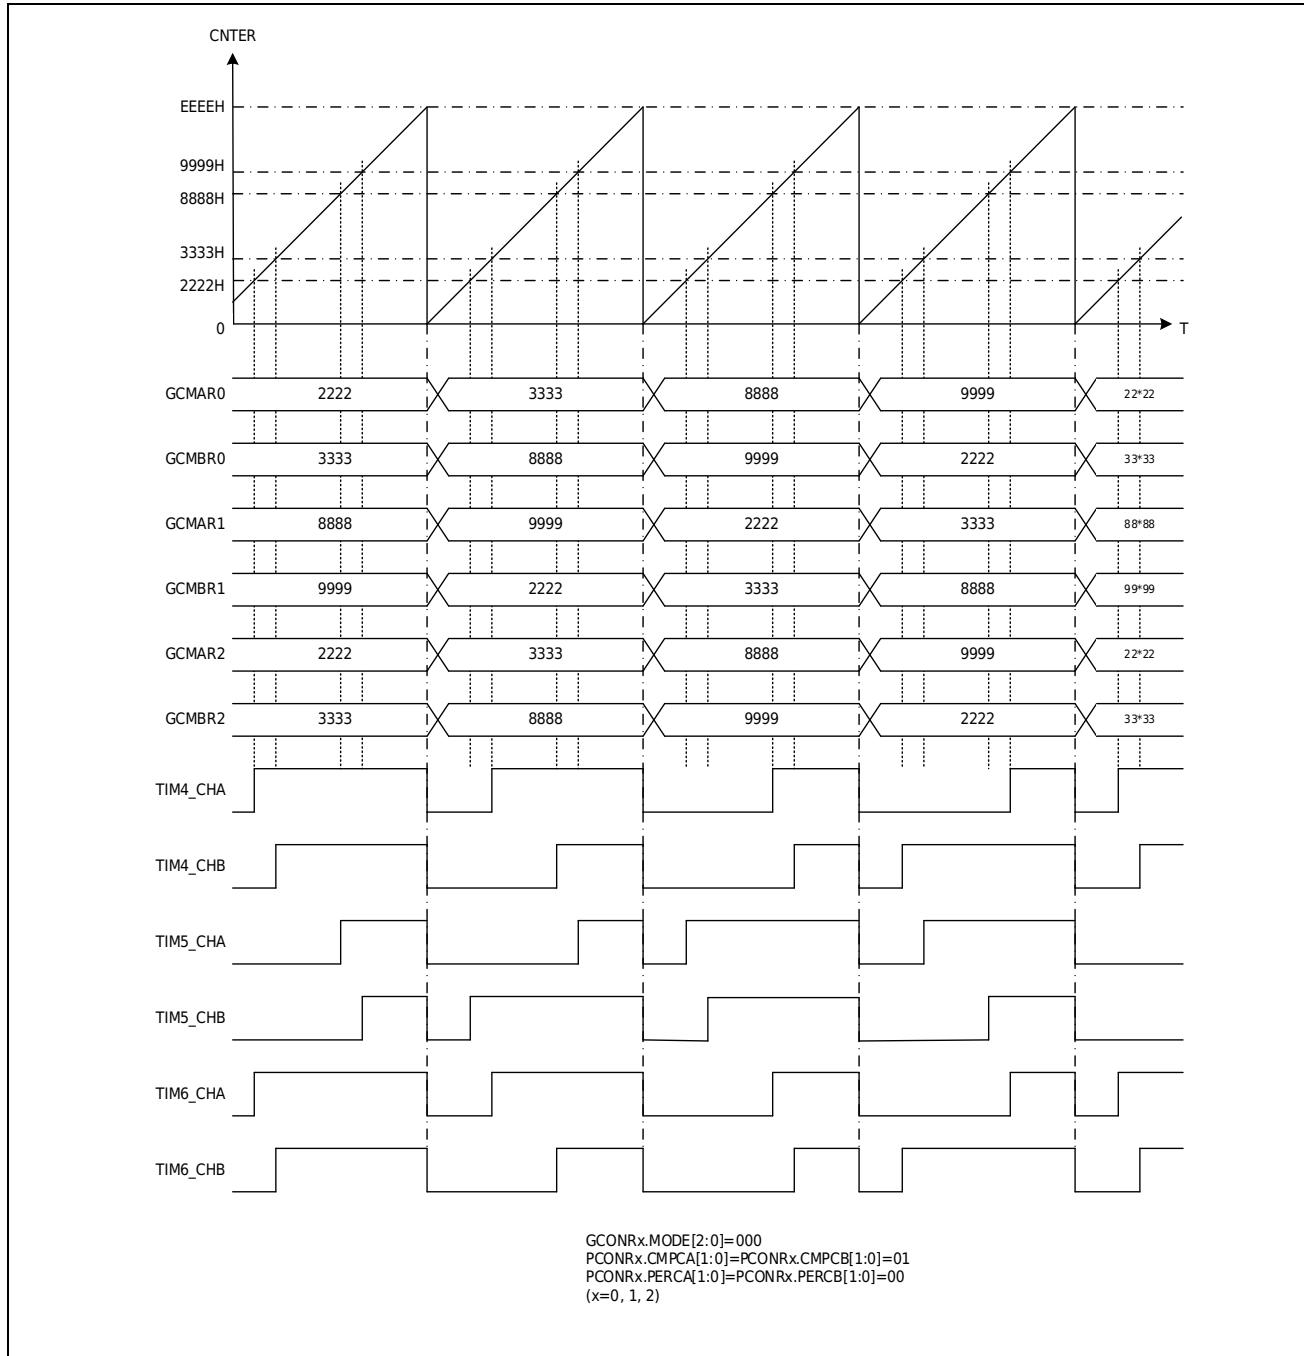

Figure 16-14 6-phase PWM wave

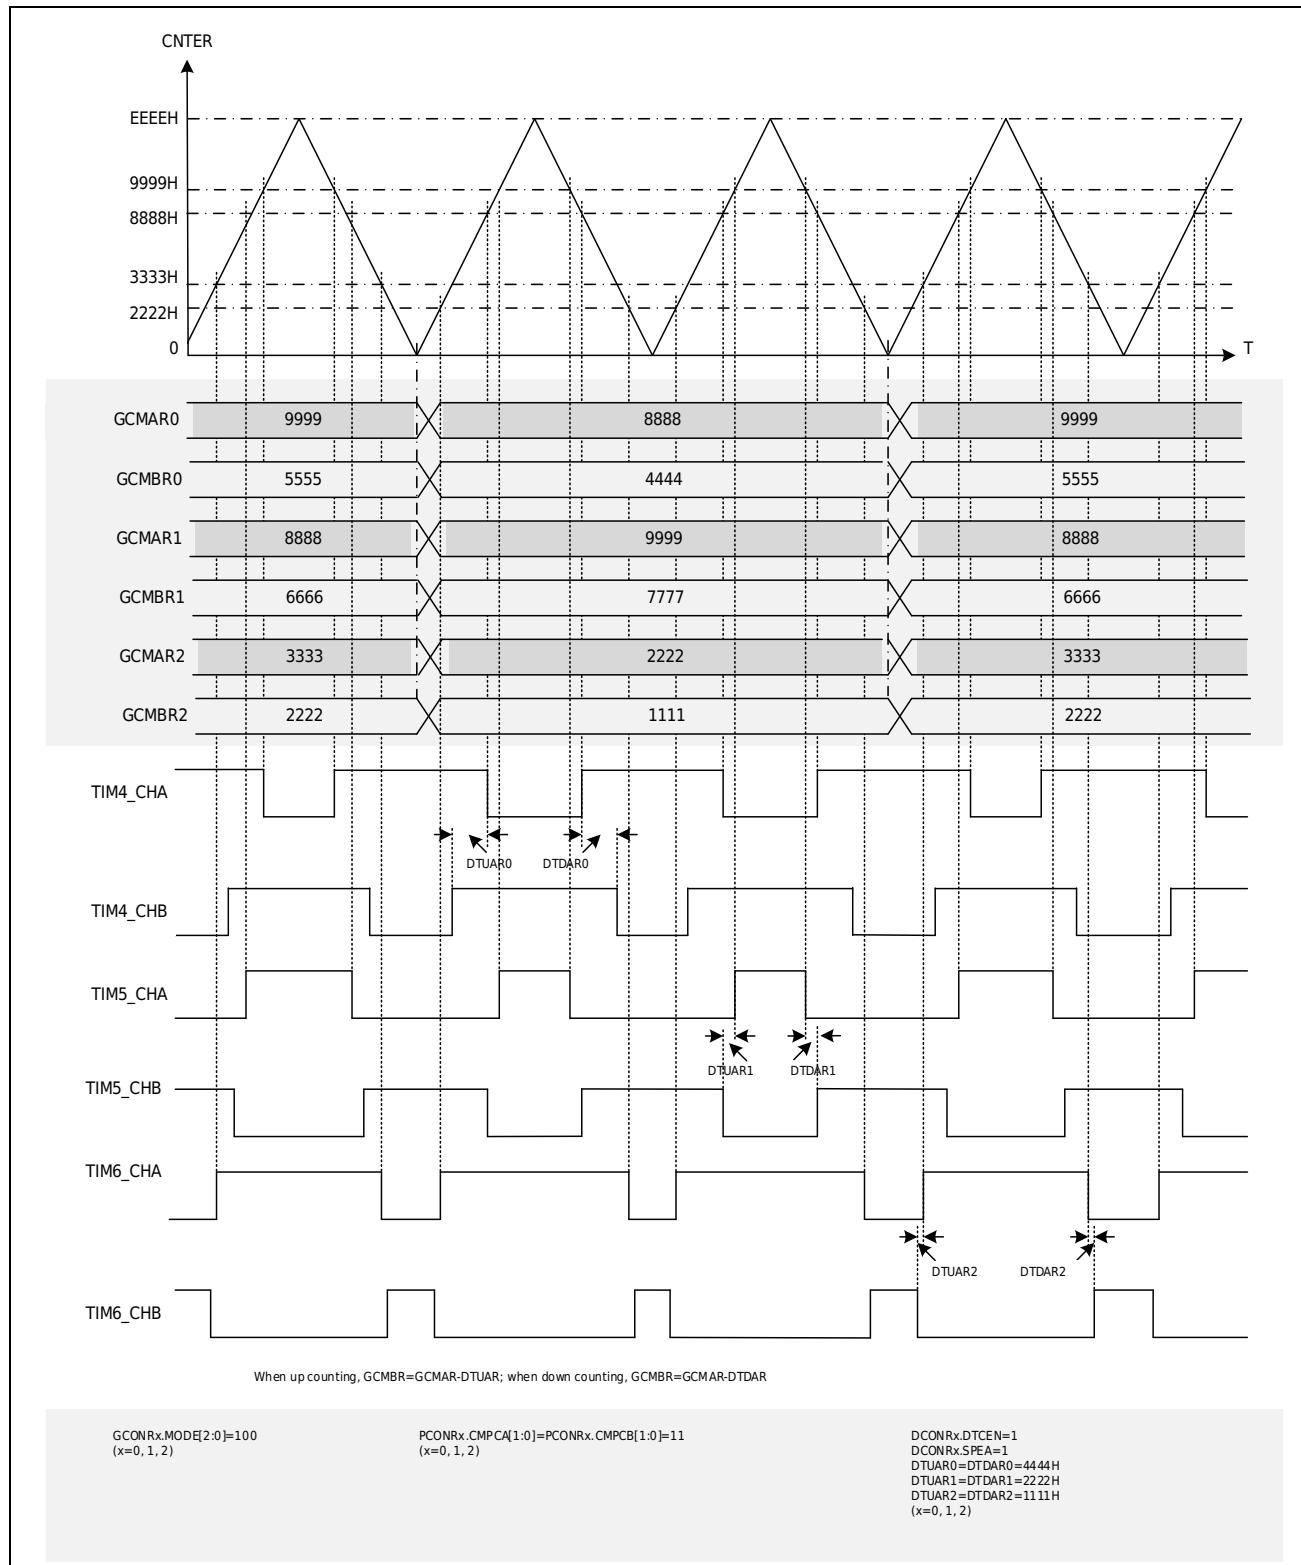

Figure 16-15 Three-phase complementary PWM wave output with dead time in triangular wave A mode

16.2.9 Orthogonal coding count

Treating CHxA input as AIN input, CHxB input as BIN input, and any input in TIMTRIA-D as ZIN input, the Advanced Timer can realize the quadrature encoding count of three inputs.

AIN and BIN of one timer can realize the position counting mode; the combined action of AIN, BIN and ZIN of two timers can realize the revolution counting mode, one timer is used for position counting, and the other timer is used for revolution counting.

In revolution counting mode, every combination of two timers (combination of timers 4 and 5, timer 4 as a position counting unit, timer 5 as a revolution counting unit) realizes position counting and revolution counting respectively.

AIN and BIN are realized by setting the orthogonal relationship between CHxA and CHxB in the hardware increment event selection register (HCUPR) and the hardware decrement event selection register (HCDOR); the input action of ZIN is cleared by setting the hardware of the position unit The event selection register (HCLRR) realizes clearing the position counter of the position counting unit, and realizes the counting of the revolution counter of the revolution counting unit by setting the hardware increment event selection register (HCUPR) of the revolution unit.

16.2.9.1 Position counting mode

The quadrature encoding position mode refers to the realization of basic counting function, phase difference counting function and direction counting function according to the input of AIN and BIN.

Basic count

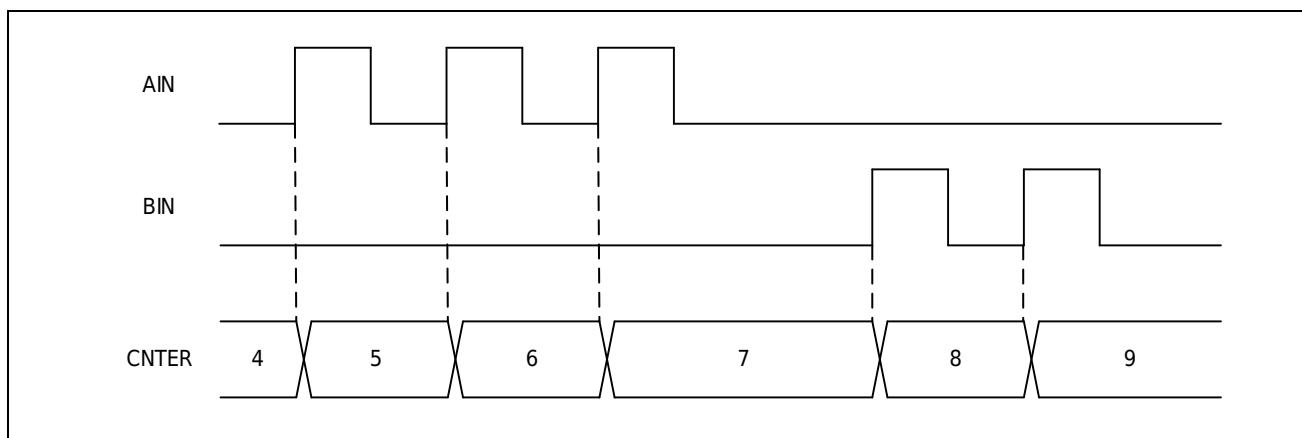

Figure 16-16 Basic counting action in position mode

By setting the HCUPR and HCDOR registers, various ways of phase difference counting can be flexibly realized.

Phase difference count

Phase difference counts are counted according to the phase relationship between AIN and BIN. According to different settings, 1-fold counting, 2-fold counting, 4-fold counting, etc. can be realized, as shown in Figure 16-17~Figure 16-19 in the following figure.

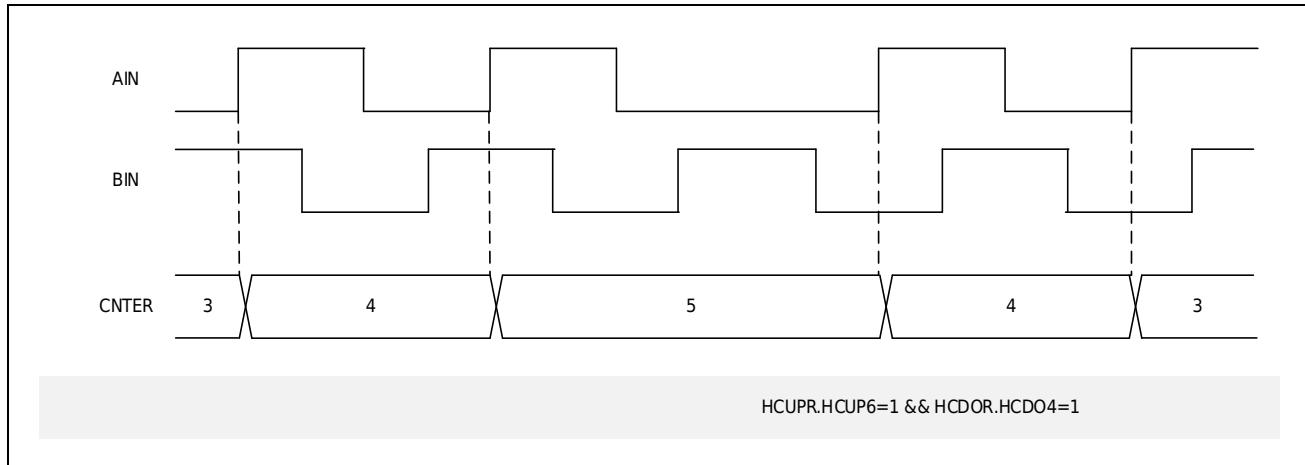

Figure 16-17 Phase difference counting action setting in position mode (1 time)

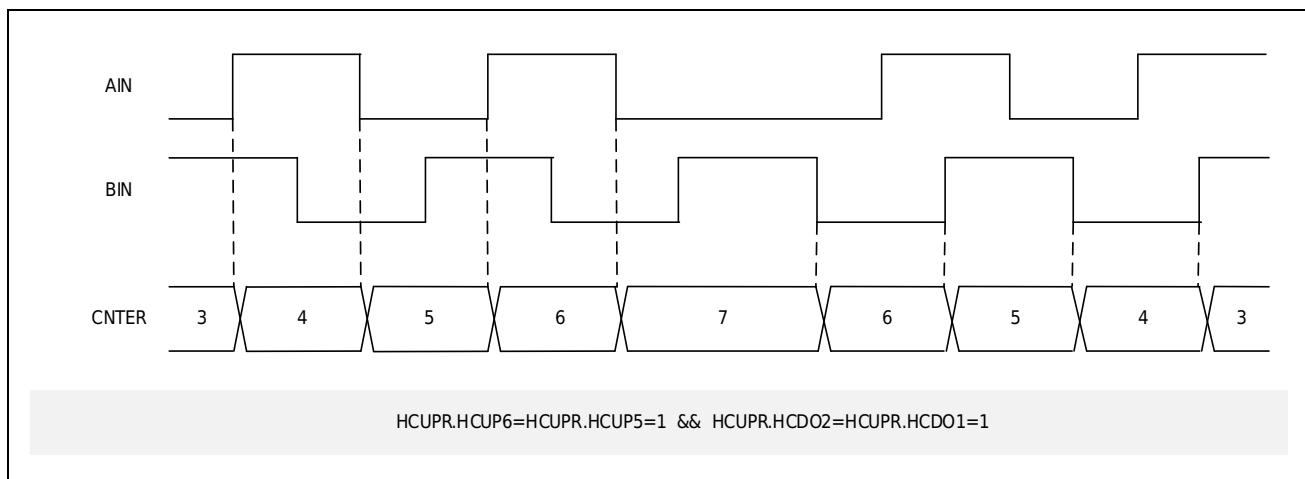

Figure 16-18 Phase difference counting action setting in position mode (2 time)

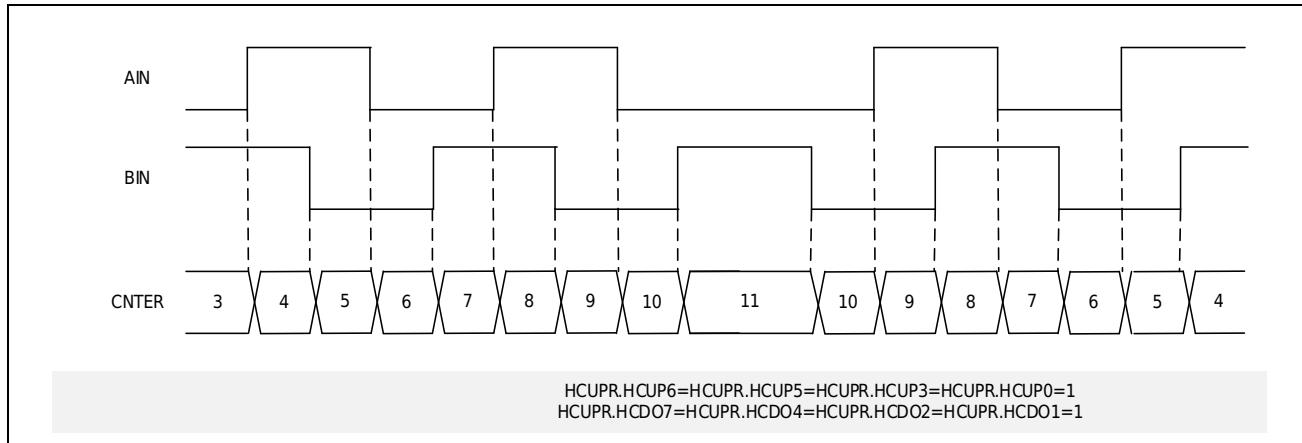

Figure 16-19 Phase difference counting action setting in position mode (4 time)

Direction count

Direction counting refers to setting the input state of AIN as direction control, and using the input of BIN as clock counting, as shown in Figure 16-20.

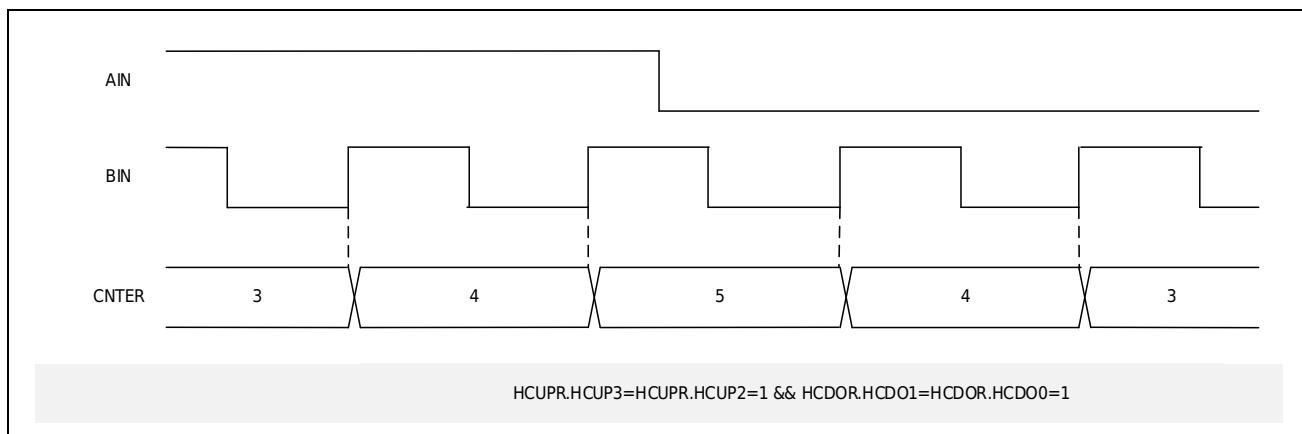

Figure 16-20 Direction counting action in position mode

16.2.9.2 Revolution mode

Orthogonal encoding revolution mode refers to the addition of ZIN input events on the basis of AIN and BIN counts to realize the judgment of the number of revolutions, etc. In the revolution mode, according to the counting method of the revolution counter, the Z phase counting function, the position counter output counting function and the Z phase counting and position counter output mixed counting function can be realized. That is to use two Advanced Timers to realize this function.

Z phase count

Z-phase counting refers to the counting action that the revolution counting unit counts and the position counting unit is cleared according to the input of ZIN.

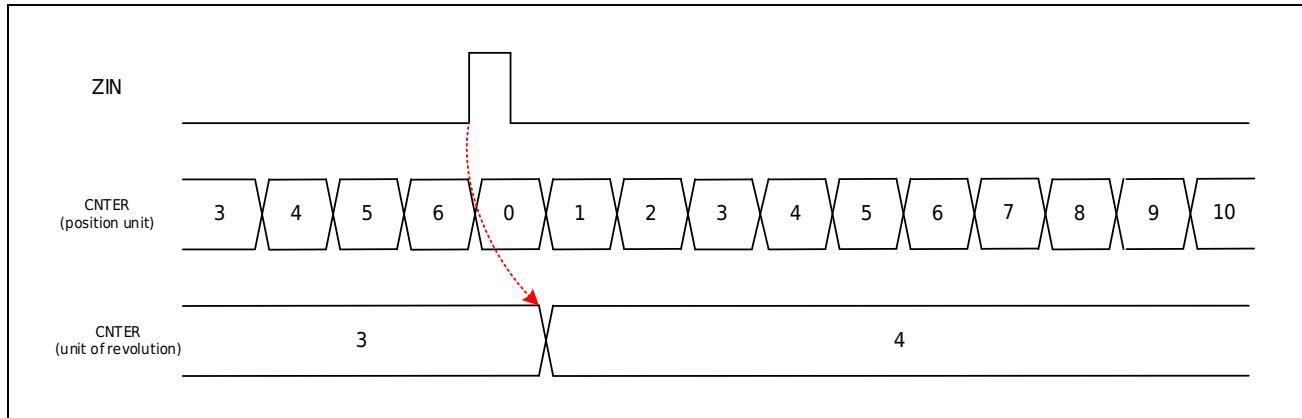

Figure 16-21 Phase Z counting action in revolution mode

Position overflow count

Position overflow counting means that when the counting of the position counting unit overflows or underflows, an overflow event is generated, thereby triggering the counter of the revolution counting unit to count once (in this counting mode, the input of ZIN does not perform the counting action of the revolution counting unit and clearing action of the position counting unit).

The overflow event of the position counting unit realizes the counting of the revolution counting unit through the linkage gating of the AOS module, and the position overflow counting can be realized. The increment (decrement) event selection register (HCUPR or HCDOR) of the hardware increment (decrement) event selection register (HCUPR or HCDOR) of the revolution counting unit selects 1 bit in Bit16:Bit19, and the AOS module sets the event source of the corresponding increment (decrement) event It is the count overflow event of the position counting unit, please refer to the AOS chapter for details. As shown in Figure 16-22.

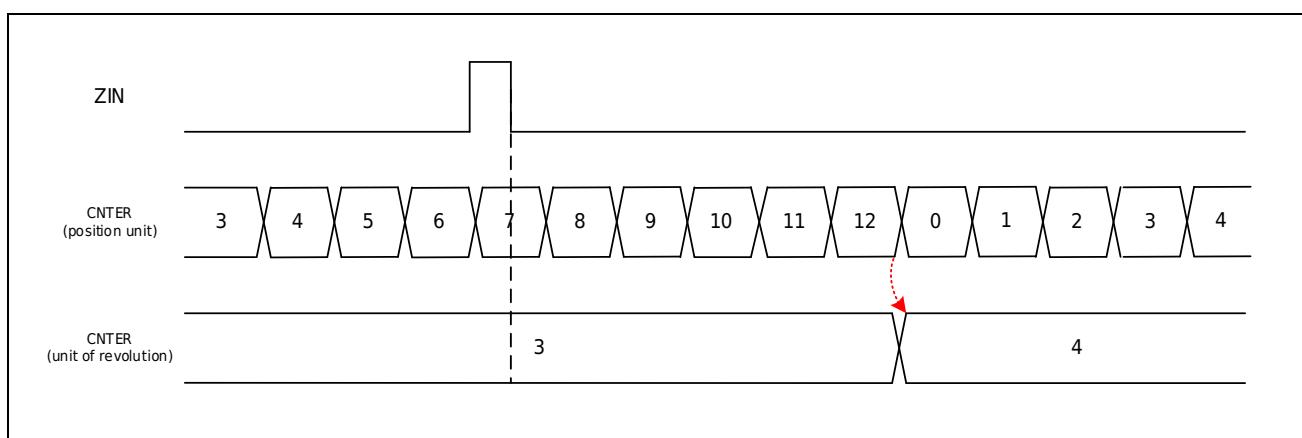

Figure 16-22 Position counter output counting action in revolution mode

mixed count

Mixed counting refers to the counting action that combines the above two counting methods of Z-phase counting and position overflow counting, and its realization method is also a combination of the above two counting methods. As shown in Figure 16-23.

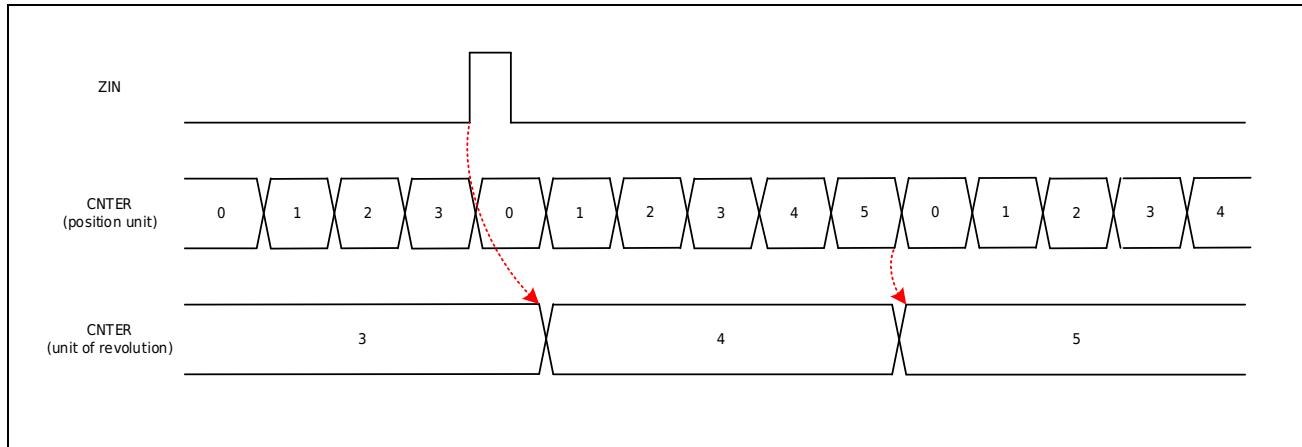

Figure 16-23 Z-phase counting and position counter output mixed counting action in revolution mode

Z phase motion shielding

In the Z-phase counting function or mixed counting function of the revolution counting mode, it can be set within a few cycles after the overflow point or underflow point of the position counter (GCONR.ZMSK[0:1] setting), ZIN The effective input mask of the input is disabled, and the counting of the revolution counting unit and the clearing of the position counting unit are not performed.

When the GCONR.ZMSKPOS of the general control register (GCONR) of the position counting unit is 1, the Z-phase masking function of the position counting unit is enabled, and the number of cycles of Z-phase masking is set by GCONR.ZMSK; the general control register of the revolution counting unit (When GCONR.ZMSKREV of GCONR) is 1, the Z-phase shielding function of the revolution counting unit is enabled.

Figure 16-24 is when the revolution counting mode is mixed counting, when there is a ZIN phase input within 4 counting cycles after the counting overflow of the position counting unit, the action of the ZIN phase input is invalid, that is, the revolution counting unit does not count, and the position counting unit does not reset ;The subsequent ZIN phase input works normally.

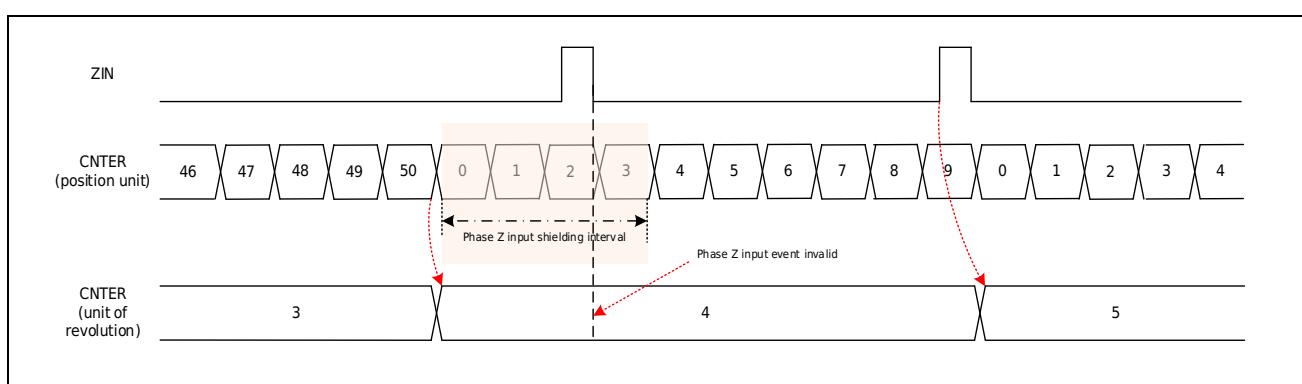

Figure 16-24 Revolution counting mode - Mixed counting Z-phase shielding action example 1

Figure 16-25 shows that when the revolution counting mode is mixed counting, the counting direction changes in the third cycle after the position counting unit overflows, and the masking cycle of the 4 cycles set at this time becomes invalid (the actual ZIN phase masking function remains up to 3 cycles), start counting down. After the counting underflow occurs in the position counting unit, the ZIN phase shielding function is re-opened and becomes invalid after 4 cycles. During the masking period of the ZIN phase, the input function of the ZIN phase is invalid, that is, the revolution counting unit does not count, and the position counting unit does not clear; the subsequent ZIN phase input operates normally.

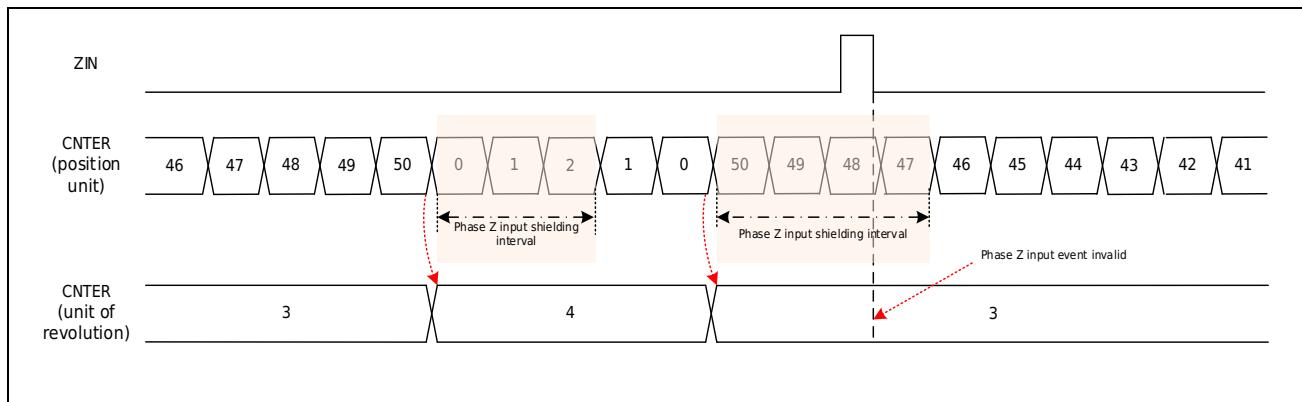

Figure 16-25 Revolution counting mode - Mixed counting Z-phase shielding action example 2

16.2.10 Periodic interval response

The general comparison reference value registers (GCMAR~GCMDR) of Timer4/5/6 can respectively generate special valid request signals when the counting comparison matches, and send them to the AOS module for associated actions with other modules.

The request signal can generate an effective request signal every several cycles. By setting the VPERR.PCNTS bit of the valid period register (VPERR) to specify how many cycles the request signal is valid once, even if the count value is equal to the value of the comparison reference value register GCMAR or GCMBR in other cycles, no valid signal will be output request signal.

If the timer is stopped and restarted when using the interval response function, please configure VPERR.PCNTE [1:0]=00 before stopping the timer. Otherwise, there may be a deviation in the time when the interval valid request signal is first generated after restarting.

Figure 16-26 shows an example of the operation of the periodic interval valid request signal.

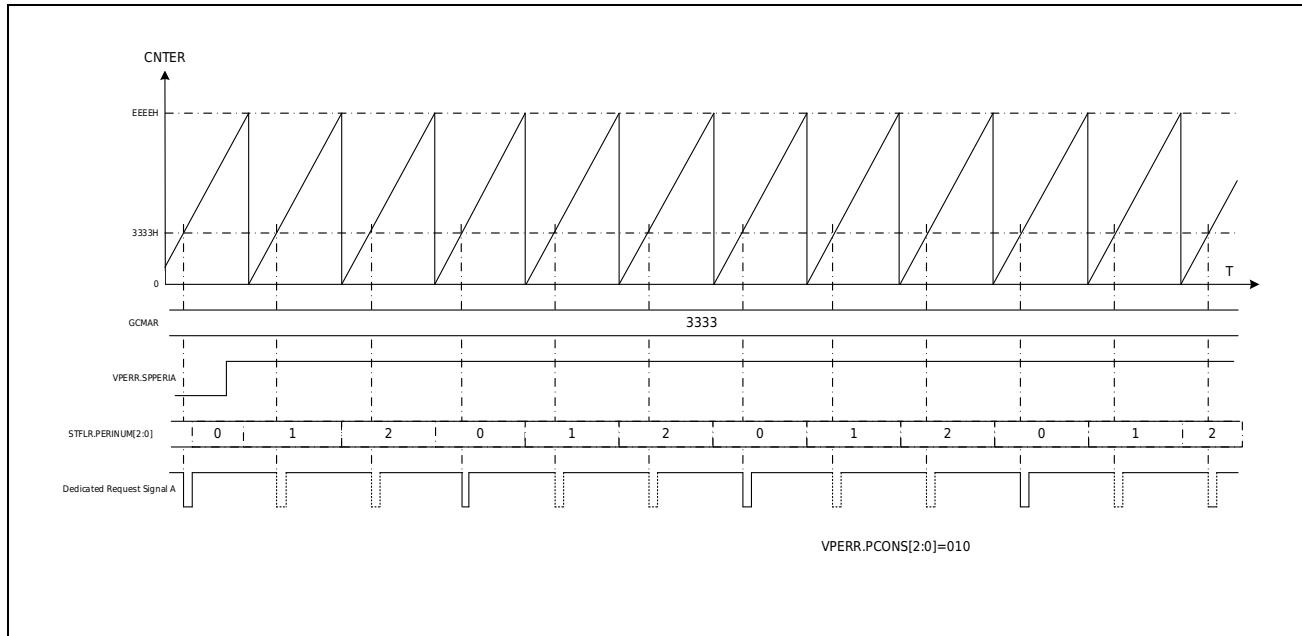

Figure 16-26 Cycle Interval Valid Request Signal Action

16.2.11 Protection mechanism

Advanced Timer can protect and control the output state of the port.

Advanced Timer has 4 shared ports to output invalid event interfaces, these 4 interfaces are connected to 4 groups of brake events output by the brake control module. The abnormal condition events gated on each interface can be set from the brake control, and when abnormal conditions are detected on these interfaces, the control of the general PWM output can be realized.

During the normal output period of the port, if a braking event from the brake control is detected, the output state of the port can be changed to a preset state. When an abnormal brake control event occurs at the general-purpose PWM output port, the state of the port can change to output high-impedance state, output low level or output high level (determined by the settings of PCONR.DISVALA and PCONR.DISVALB).

For example, if PCONR.DISSELLA[1:0]=01&PCONR.DISVALA=01 is set, then during the normal output period of CHxA port, if a brake event occurs on output invalid condition 1, the output of CHxA port will become a high-impedance state.

16.2.12 Interrupt Description

Timer4/5/6 each contain 3 types of 9 interrupts in total. They are 4 common count comparison match interrupts (including 2 capture input interrupts), 2 count cycle match interrupts, and 1 dead zone time error interrupt.

16.2.12.1 Count comparison match interrupt

4 general -purpose comparison reference registers (GCMAR-GCMDR), which can be compared with the count value to generate a comparison match valid signal. When the count compare matches,

the STFLR.CMAF~STFLR.CMDF bits in the status flag register (STFLR) will be set to 1 respectively. At this time, if the corresponding bit in ICONR.INTENA~ICONR.INTEND of the interrupt control register (ICONR) is set to 1 to enable the interrupt, the corresponding interrupt request will also be triggered.

The capture input action occurs when the capture input valid condition selected by the hardware capture event selection register (HCPAR, HCPBR) occurs. At this time, if the ICONR.INTENA or ICONR.INTENB bit of the interrupt control register (ICONR) is set to 1 to enable the interrupt, the corresponding interrupt request will be triggered.

16.2.12.2 Count cycle match interrupt

When the sawtooth wave counts up to the overflow point, the sawtooth wave counts down to the underflow point, the triangle wave counts to the valley point or the triangle wave counts to the peak point, the STFLR.1. At this time, if the ICONR.INTENOVF bit and ICONR.INTENUDF bit of the interrupt control register (ICONR) are set to enable the interrupt, the counting cycle match interrupt can be triggered at the corresponding time point.

16.2.12.3 Dead time error interrupt

the dead time reference register (DTUAR, DTDAR) is loaded into the general comparison reference register (GCMBR), if the cycle limit is exceeded, a dead time error will be generated, and the STFLR.DTEF of the status flag register (STFLR) bit will be set to 1. At this time, if the ICONR.INTENDE bit of the interrupt control register (ICONR) is set to enable the interrupt, the dead time error interrupt will be triggered at this moment.

16.2.13 DMA

Timer supports software and hardware to trigger DMA for data transfer. Data is supported to be written to the timer from other locations, or read and written from the timer to other locations. It can be applied to the automatic handling of data after data capture and the automatic adjustment of the pulse width changing the period value or duty cycle. Each timer has two DMA requests, A request trigger source can choose general comparison capture A, C, special comparison A, count overflow, B request trigger source can choose general comparison capture B, D, special comparison B, count down overflow.

IDREQ	Interrupt Signal of Peripheral
26	TIM4A
27	TIM4B
28	TIM5A
29	TIM5B
30	TIM6A
31	TIM6B

TIMxA _ Trigger source selectable compare capture A, C, count overflow, dedicated compare A

TIMxB _ Trigger source selectable compare capture B, D, count underflow, dedicated compare B

16.2.14 brake protection

When invalid conditions 0~3 can be set, configure PCONR.DISVALA, PCONR.DISVALB. When the invalid condition is valid, the hardware automatically changes the port state to the preset state (high level, low level, high impedance state, and maintains normal output).

16.2.14.1 Port brake and software brake

After the port is controlled by polarity selection and effectively enabled, it is digitally filtered and synchronized to generate a port brake flag; the port brake flag is used as the invalid condition of the Advanced Timer 3. The port brake flag needs to be cleared by software.

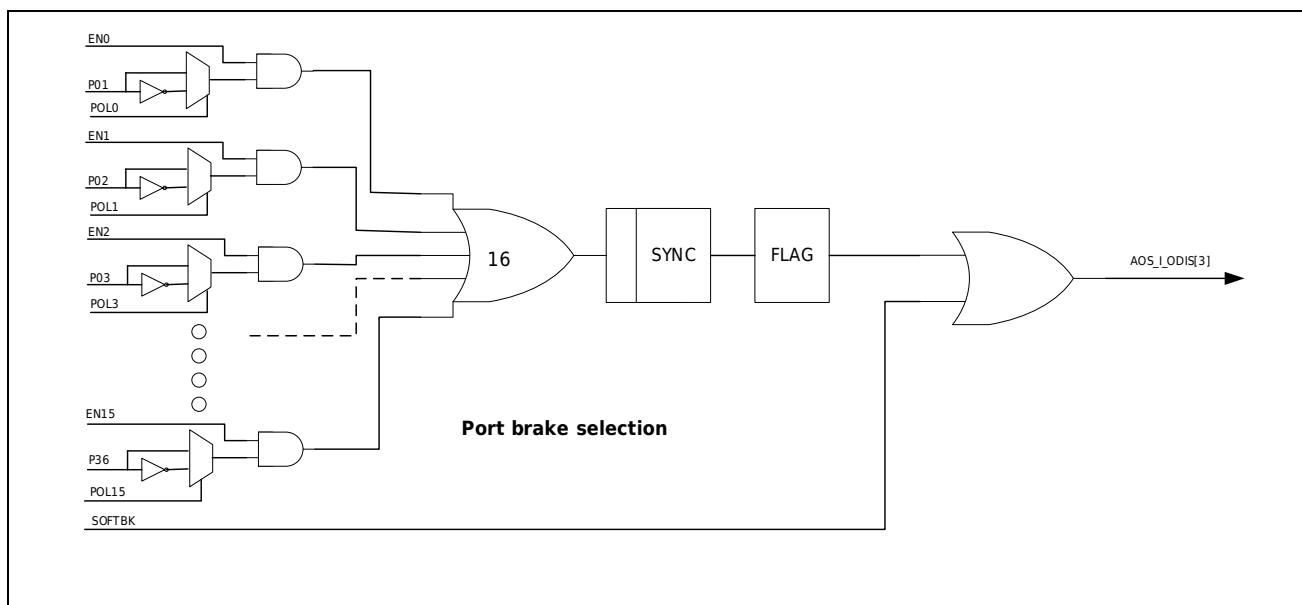

Figure 16-27 Schematic diagram of port braking and software braking

16.2.14.2 Automatic braking in low power mode

the PWM will not work normally after the clock is stopped. Low power consumption mode controls PWM brake as invalid condition 2 of Advanced Timer.

16.2.14.3 Output level same high and same low brake

The output level is monitored by the level, and after it is effectively enabled, it is synchronized to generate the same high and low brake flag; the port brake flag is used as the invalid condition 1 of the Advanced Timer. The same high and same low brake flag needs to be cleared by software.

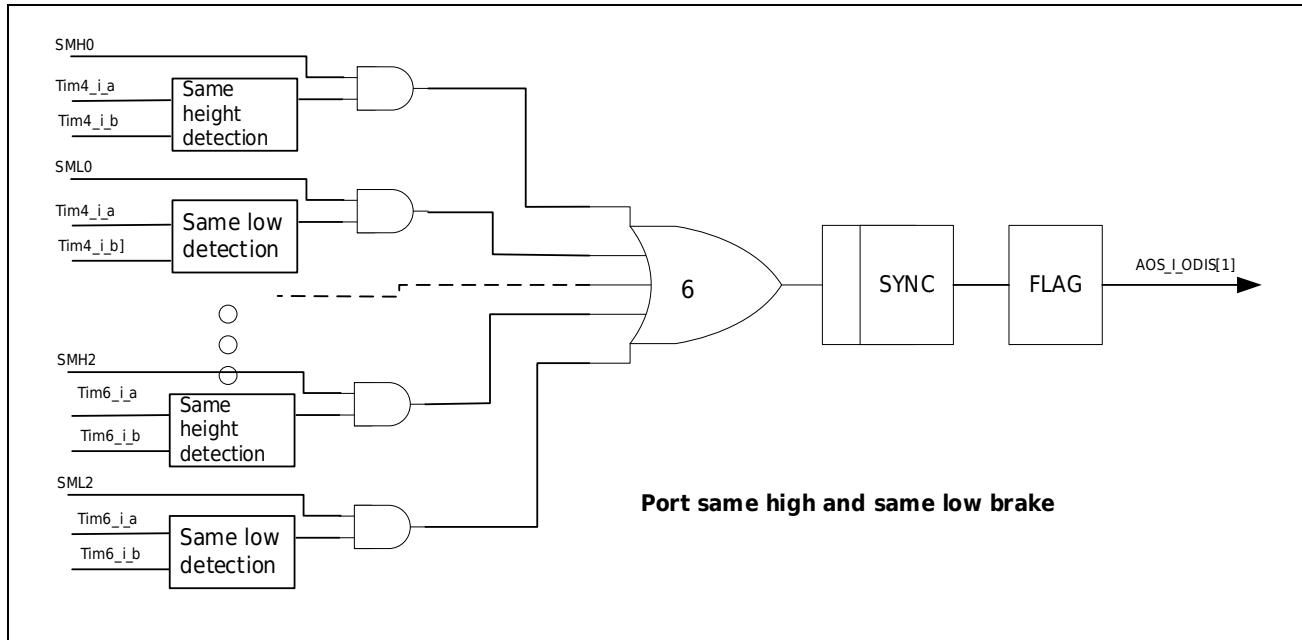

Figure 16-28 Output same high and same low brake schematic diagram

16.2.14.4 VC brake

VC0, VC1, VC2 interrupt flags are enabled as the invalid condition 0 of the Advanced Timer.

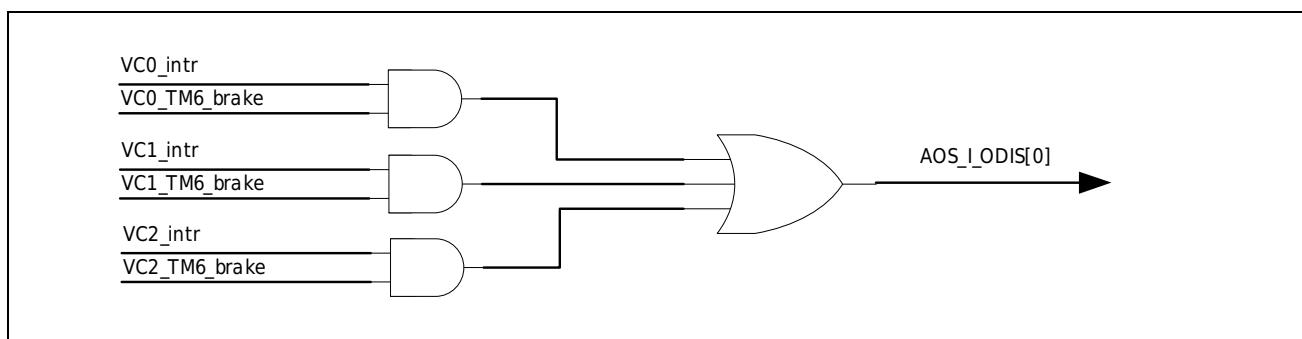

Figure 16-29 VC brake control diagram

16.2.15 interconnection

16.2.15.1 interrupt trigger output

Because one interrupt of Timer4/5/6 contains multiple interrupt sources. The interrupt signals for controlling the trigger ADC and controlling the AOS have separate control, and different sources can be selected, such as overflow, underflow, 4 compare matches, and any interrupt source with a total of 6 TIMx interrupt sources as the trigger condition.

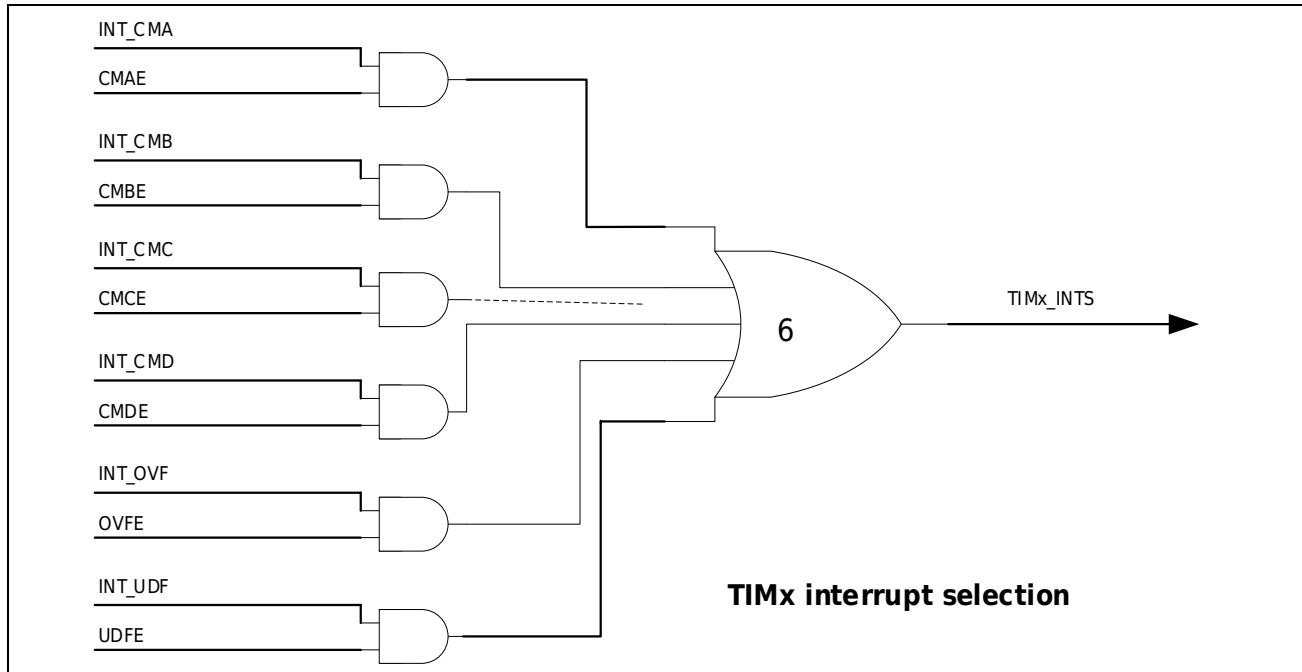

Figure 16-30 Timer4/5/6 interrupt selection

16.2.15.2 AOS trigger

AOS is the internal signal of the system, which can trigger the Advanced Timer's counter to start, stop, clear, add 1, subtract 1 and other functions after selection control. Advanced Timer has 4 AOS triggers, and each trigger can select the interrupt source of different modules. The selected signal generates a single pulse trigger input to the Advanced Timer to control the start, stop, and reset of the counter of the Advanced Timer.

Timer4/5/6 internally uses registers to select different AOS_I_TRIG as its own trigger signal. If you can use the HSTAR register, you can use an interrupt to trigger the hardware start of the corresponding timer.

Table 16-3 AOS source selection

16.2.15.3 Port Trigger TRIGA-TRIGD

The port trigger can control the hardware start, stop, clear, capture, counter plus and minus counting functions of the Advanced Timer, and the digital filter function is optional, and the port can be configured as any port of the chip.

Table 16-4 Port trigger selection

17 Watchdog Timer (WDT)

17.1 Introduction to WDT

WDT can be used to detect and resolve failures caused by software errors. When the WDT counter reaches the set overflow time, it will trigger an interrupt or generate a system reset. WDT is driven by a dedicated 10KHz on-chip oscillator.

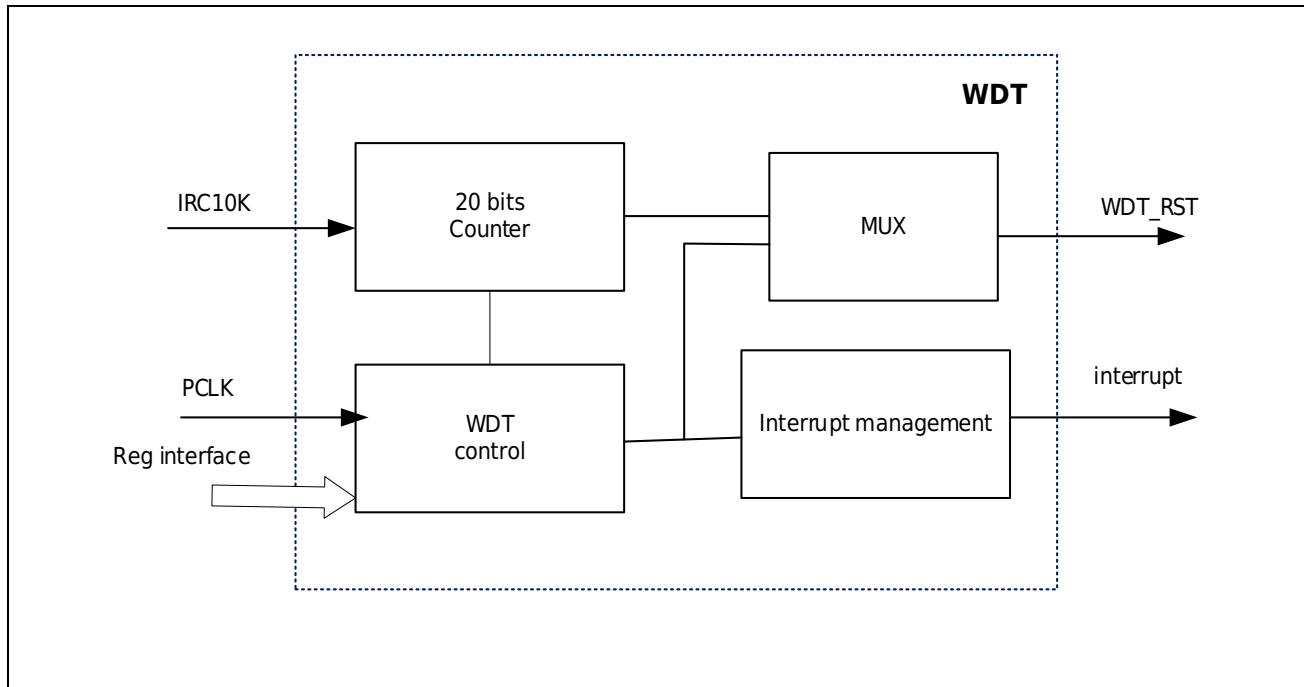

Figure 17-1 Overall block diagram of WDT

17.2 WDT Functional Description

- 20Bit free-running up counter, the overflow time can be configured from 1.6ms to 50s.
- Action after overflow can be configured as interrupt or reset.
- The WDT clock is provided by an independent RC oscillator, which can work in Sleep and DeepSleep modes.
- WDTCON register can only be modified when the WDT is not started to prevent unintentional modification of the WDT configuration after startup.

17.2.1 Interrupt generated after WDT overflow

In this mode, WDT will generate interrupt periodically according to the set time. WDT interrupt flag needs to be cleared in the interrupt service routine.

The configuration method is as follows:

Step1: Configure WDT_CON. WOV, select WDT timer overflow time.

Step2: Set WDT_CON. WINT_EN to 1, select WDT to generate an interrupt after overflow.

Step3: Enable the WDT interrupt in the NVIC interrupt vector table.

Step4: Write 0x1E and 0xE1 to the WDT_RST register in sequence to start the WDT timer.

Step5: Write 0x1E and 0xE1 to the WDT_RST register in the interrupt service routine to clear the interrupt flag.

17.2.2 Reset after WDT overflow

In this mode, the Reset signal will be generated after the WDT counter overflows, which will reset the MCU. User program needs to clear the WDT counter before WDT overflow, so as to avoid WDT reset.

The configuration method is as follows:

Step1: Configure WDT_CON. WOV, select WDT counter overflow time.

Step2: Set WDT_CON. WINT_EN to 0, select WDT to generate reset after overflow.

Step3: Write 0x1E and 0xE1 to the WDT_RST register in sequence to start the WDT timer.

Step4: Before the WDT overflows, write 0x1E and 0xE1 to the WDT_RST register to clear the WDT counter.

Note:

- Since the WDT oscillator is a low-precision RC oscillator, it is strongly recommended to clear the WDT before the WDT counter reaches half of the overflow value.

17.3 WDT register description

Base address 0X40000F00

18 General Synchronous Asynchronous Transceiver (UART)

18.1 Introduction

The Universal Synchronous Asynchronous Receiver (UART) can flexibly exchange full-duplex data with external devices, and it supports synchronous one-way communication, single-wire half-duplex communication, and multi-processor communication. It is often used in short-distance, low-speed serial communication. The UART provides a variety of baud rates through a programmable baud rate generator. UART supports multiple working modes.

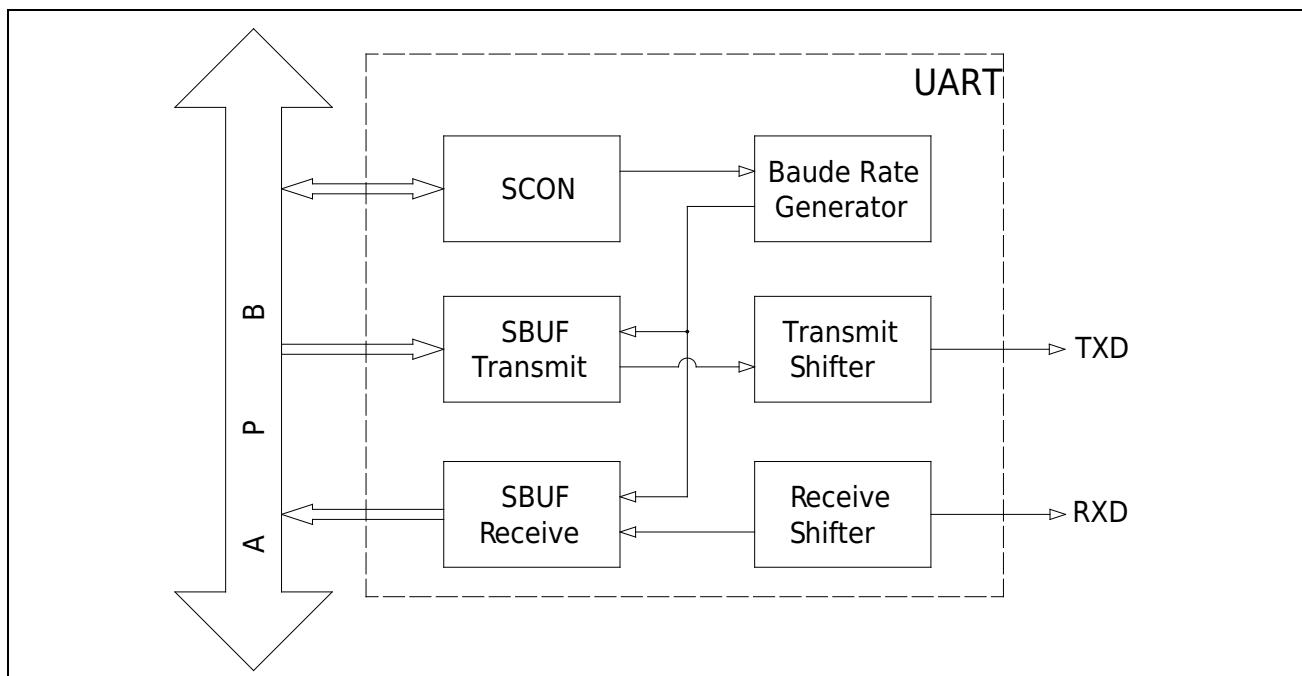

Figure 18-1 Block Diagram

18.2 Main characteristics

General purpose UART module supports the following basic functions:

- Full-duplex transmission, half-duplex transmission, single-wire half-duplex transmission
- Programmable serial communication function
 - Two character lengths: 8 bits, 9 bits
 - Three checkout methods: no checkout, odd checkout, even checkout
 - Three stop lengths: 1 bit, 2 bits, 1.5 bits
- 16-bit baud rate generator
- Multi-machine communication
- Hardware address recognition
- Hardware flow control
- DMA transmission handshake

18.3 Functional description

18.3.1 Operating mode

UART supports multiple working modes: synchronous half-duplex mode, asynchronous full-duplex mode, and single-wire half-duplex mode. Through the combination of `UARTx_SCON.SM` and `UARTx_SCON.HDSEL`, various working modes can be configured.

18.3.1.1 Mode0~Mode3 function comparison

Configure `UARTx_SCON.SM` to select different transmission modes: Mode0~Mode3. The main function comparison of these four working modes is shown in the table below:

Table 18-1 Mode0/1/2/3 Data Structure

Operating mode		Transmission bit width	Data composition	Baud rate
Mode0	Synchronous mode Half duplex	8bit	Data(8bit)	$\text{BaudRate} = \frac{f_{\text{PCLK}}}{12}$
Mode1	Asynchronous mode Full duplex	10~11bit	Start (1bit) + Data(8bit) + Stop(1~2bit)	$\text{BaudRate} = \frac{f_{\text{PCLK}}}{\text{OVER} * \text{SCNT}}$
Mode2	Asynchronous mode Full duplex	11~12bit	Start (1bit) + Data(8bit) + B8(1bit) + Stop(1~2bit)	$\text{BaudRate} = \frac{f_{\text{PCLK}}}{\text{OVER}}$
Mode3	Asynchronous mode Full duplex	11~12bit	Start (1bit) + Data(8bit) + B8(1bit) + Stop(1~2bit)	$\text{BaudRate} = \frac{f_{\text{PCLK}}}{\text{OVER} * \text{SCNT}}$

Note:

- Mode0 can only be used as a host to send UART synchronous shift clock, and cannot be used as a slave to receive UART synchronous shift clock input from the outside.
- f_{PCLK} Represents the frequency of the current PCLK.
- The definition of OVER is detailed in `UARTx_SCON`.
- `UARTx_SCNT` for the definition of SCNT.
- The B8 data bit is special and has different meanings in different applications, please refer to the following table:

Table 18-2 B8 Data Meaning

Application Scenario	UARTx_SCON.ADRDET	UARTx_SCON.B8CONT[1:0]	B8 Data Meaning
Parity	--	01/10	When receiving, B8 is the parity bit of the received 8-Bit data; When sending, B8 is the parity bit of the 8-Bit data to be sent;
Multi-machine communication	1	--	B8=1, it means that it is currently an address frame; B8=0, it means the current data frame;
Other	0	00/11	8th bit of receive / send number

Note:

- When the multi-machine communication mode is turned on, the parity check of the received data is automatically closed; the parity check of the sent data is still controlled by B8CONT.

18.3.1.2 Mode0 data sending and receiving instructions

When sending data, clear the `UARTx_SCON.REN` bit and write the data into the `UARTx_SBUF` register. At this time, the sending data is output from RXD (low bit first, high bit later), and the synchronous shift clock is output from TXD.

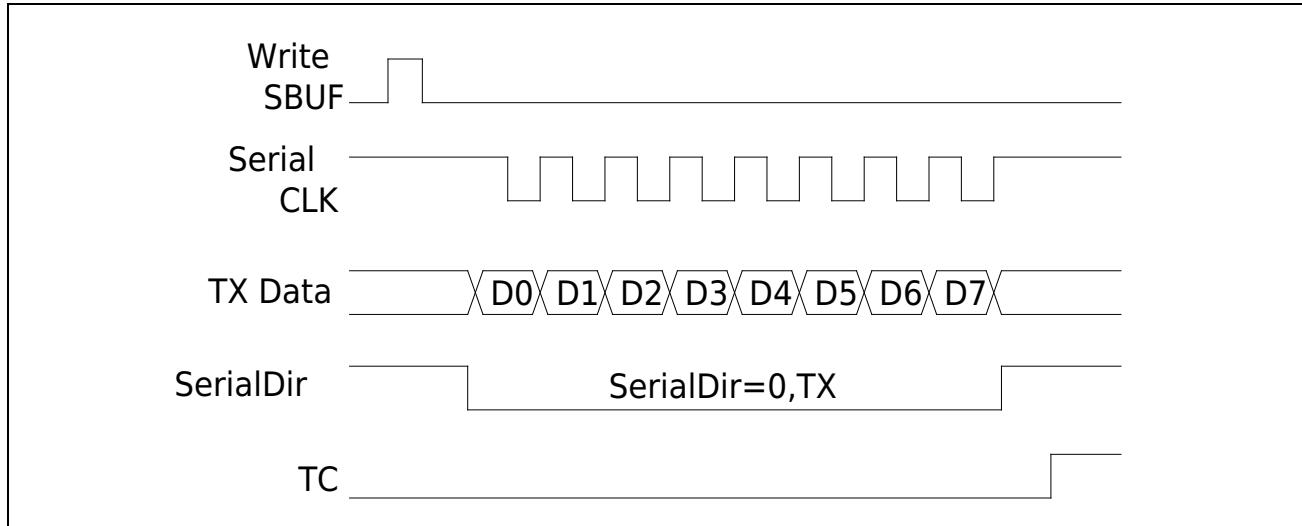

Figure 18-2 Mode0 sending data

When receiving data, set the `UARTx_SCON.REN` bit and clear the `UARTx_ISR.RC` bit. When reception is complete, data can be read from the `UARTx_SBUF` register. At this time, the received data is input from RXD (low bit first, high bit later), and the synchronous shift clock is output from TXD.

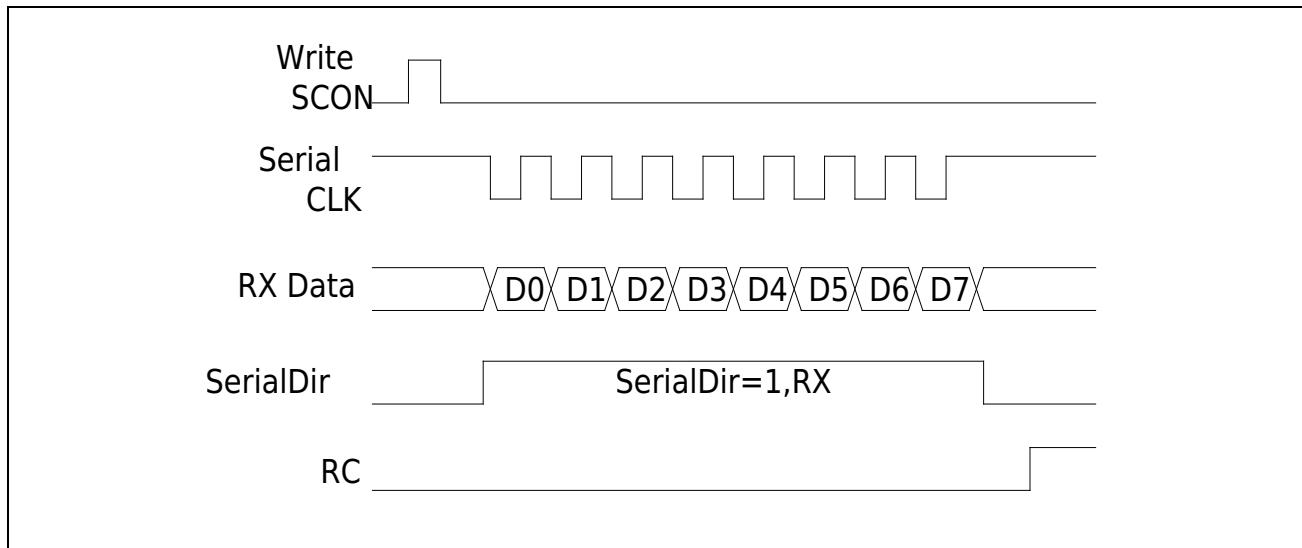

Figure 18-3 Mode0 receiving data

18.3.1.3 Mode1 data sending and receiving instructions

When sending data, it has nothing to do with the value of `UARTx_SCON.REN`, write the sent data into the `UARTx_SBUF` register, and the data will be shifted out from `TXD` (low bit first, high bit later).

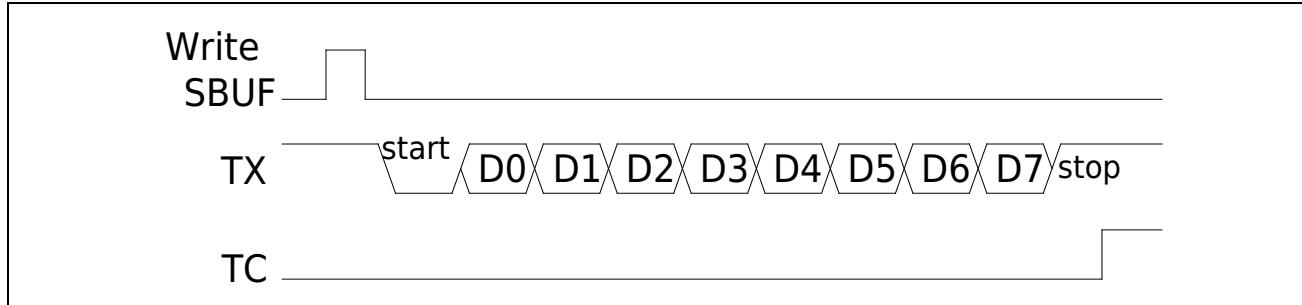

Figure 18-4 Mode1 sending data

When receiving data, set the `UARTx_SCON.REN` bit to 1 and clear the `UARTx_ISR.RC` bit to 0. Start to receive the data on `RXD` (low bit first, high bit later), when the reception is completed, it can be read from the `UARTx_SBUF` register.

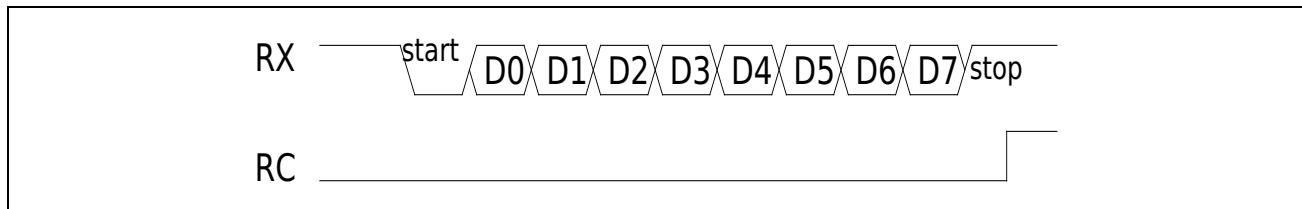

Figure 18-5 Mode1 receiving data

18.3.1.4 Mode2 data sending and receiving instructions

When sending data, it has nothing to do with the value of `UARTx_SCON.REN`, write the sent data into the `UARTx_SBUF` register, and the data will be shifted out from `TXD` (low bit first, high bit later).

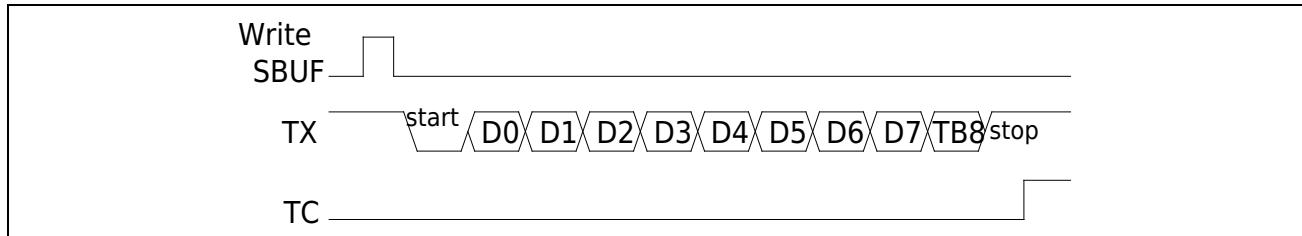

Figure 18-6 Mode2 sending data

When receiving data, you need to set the `UARTx_SCON.REN` bit to 1, and clear the `UARTx_ISR.RC` bit to 0. Start to receive the data on `RXD` (low bit first, high bit later), when the reception is completed, it can be read from the `UARTx_SBUF` register.

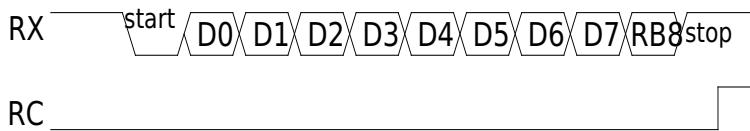

Figure 18-7 Mode2 receiving data

18.3.1.5 Mode3 data sending and receiving instructions

When sending data, it has nothing to do with the value of `UARTx_SCON.REN`, write the sent data into the `UARTx_SBUF` register, and the data will be shifted out from `TXD` (low bit first, high bit later).

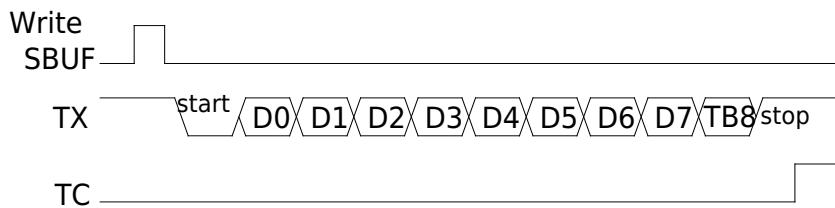

Figure 18-8 Mode3 sending data

When receiving data, set the `UARTx_SCON.REN` bit to 1 and clear the `UARTx_ISR.RC` bit to 0. Start to receive the data on `RXD` (low bit first, high bit later), when the reception is completed, it can be read from the `UARTx_SBUF` register.

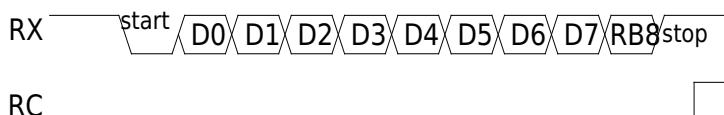

Figure 18-9 Mode3 receiving data

18.3.1.6 Description of single-wire half-duplex data transmission and reception

When `UARTx_SCON.HDSEL=1'b1`, it can enter the single-wire half-duplex transmission mode:

- The TX and RX signal lines are connected inside the module.
- The RX signal is no longer used, and the received and sent data are all completed through the TX signal. TX signal is done by hardware logic without software control.
- When the sending buffer is empty, the TX signal is always input (receiving state), once a data is filled into the sending buffer, the TX signal becomes output (sending state), when the sending is completed, the sending buffer becomes empty, and the TX signal turns to Back to typing.
- When there is no data transmission, the `TXD` pin is always in the input state. The user program needs to configure this pin as an open-drain output and connect an external pull-up resistor.

Note:

1. Even if the module is in the receiving process, as long as the sending buffer is filled with

data, the TX signal will immediately become output (transmitting state), the receiving process will be interrupted, and an incorrect received data will be obtained.

2. The similarities and differences between single-line half-duplex mode and Mode0 mode:

Same: Both use one signal to time-division multiplex to complete data transmission and reception.

Different: Mode0 is synchronous transmission with a synchronous clock, while the single-wire half-duplex mode is asynchronous transmission, all baud rate calculations still follow the baud rate formula of Mode1-2-3, only the transceiver function is multiplexed to the TX signal.

18.3.2 Baud rate generation

Mode0~Mode3 are different, as shown below for details.

$$\text{Mode0 baud rate generation formula: } \text{BaudRate} = \frac{f_{\text{PCLK}}}{12}$$

$$\text{Mode1 baud rate generation formula: } \text{BaudRate} = \frac{f_{\text{PCLK}}}{\text{OVER} * \text{SCNT}}$$

$$\text{Mode2 baud rate generation formula: } \text{BaudRate} = \frac{f_{\text{PCLK}}}{\text{OVER}}$$

$$\text{Mode3 baud rate generation formula: } \text{BaudRate} = \frac{f_{\text{PCLK}}}{\text{OVER} * \text{SCNT}}$$

Note:

- f_{PCLK} represents the frequency of the current PCLK.
- The definition of OVER is detailed in `UARTx_SCON`.
- The definition of SCNT is detailed in `UARTx_SCNT`

18.3.3 Frame error detection

When working in Mode1/2/3, UART has a frame error detection function. If the hardware does not recognize the stop bit within the expected time when receiving data, resulting in synchronization failure or excessive noise, a frame error will be detected. `UARTx_ISR.FE` is set when a framing error is detected. `UARTx_ISR.FE` should be cleared by software in time.

18.3.4 Multi-machine communication

When working in Mode2/3, set the `UARTx_SCON.ADRDET` bit to "1" to enable the multi-device communication function.

The host can use `UARTx_SBUF[8]` to distinguish whether the current sending frame is an address frame (`UARTx_SBUF[8]=1`) or a data frame (`UARTx_SBUF[8]=0`).

- When it is a data frame, the frame data will not be stored in the `UARTx_SBUF` register of the slave, and the slave will not generate a receive interrupt.
- When it is an address frame, since the automatic address recognition function in the multi-machine communication has been turned on, the slave can detect whether the received address matches its own address.
 - If the address matches, the slave will set "1" to `UARTx_ISR.RC`, set "1" to `UARTx_SBUF[8]`, and store the address frame into the `UARTx_SBUF` register at the same time. After the slave software sees `UARTx_SBUF[8]=1` and `UARTx_ISR.RC=1`, clear the `UARTx_SCON.ADEDET` bit to "0" and accept the data frame.
 - If the address does not match, it means that the master is not addressing the slave, the slave hardware keeps `UARTx_SBUF[8]` and `UARTx_ISR.RC` as "0", the software keeps the `UARTx_SCON.ADRDET` bit as "1", and continues to be in the address monitoring state.

Note: If necessary, the multi-machine communication bit can also be turned on in Mode1, and the TB8 bit is replaced by the stop bit. When the slave receives a matching address frame and a valid stop bit, `UARTx_ISR.RC` will be set to "1".

18.3.4.1 Given address

`UARTx_SADDR` register of the UART device is used to indicate the given address of its own device.

The `UARTx_SADEN` register is an address mask. When a certain bit of `UARTx_SADEN` is "0", it can define an irrelevant bit in the address and does not participate in address matching. These don't care bits increase addressing flexibility, allowing the master to address one or more slave devices simultaneously.

Note: If a unique matching address needs to be given, the `UARTx_SADEN` register must be set to 8'hFF. The given address formula looks like this:

$$\text{GivenAddr} = \text{SADDR} \& \text{SADEN}$$

18.3.4.2 Broadcast address

The broadcast address is used to address all slave devices at the same time, and the general broadcast address is 8'hFF.

$$\text{BroadCastAddr} = \text{SADDR}|\text{SADEN}$$

18.3.4.3 Example

Suppose the UARTx_SADDR and UARTx_SADEN of a slave are configured as follows:

SADDR: 8'b01101001
SADEN: 8'b11111011

Then its given address and broadcast address are as follows:

Given: 8'b01101x01
Broadcast: 8'b11111x11

It can be seen that the master can use four addresses to address the slave, namely:

8'b01101001 and 8'b01101101 (given address)
8'b11111011 and 8'b11111111 (broadcast address).

18.3.5 DMAC hardware handshake

UART module supports the hardware handshaking logic of the DMAC.

- Setting UARTx_SCON.DMACTXEN to 1 can turn on the DMAC hardware handshaking logic of UART TX. When the transmit buffer is empty, the UART will send a data transfer request TX REQ to the DMAC. DMAC receives this signal, it transfers the sending data of one frame from the DMAC source address to UARTx_SBUF. The above steps are repeated until all the data lengths configured in the DMAC are transferred.
- Setting UARTx_SCON.DMACRXEN to 1 can turn on the DMAC hardware handshaking logic of UART RX. When a frame is received, the UART will send a data transfer request RX REQ to the DMAC. DMAC receives this signal, it transfers the received data from UARTx_SBUF to the target address of DMAC. The above steps are repeated until all the data lengths configured in the DMAC are transferred.

18.3.6 Hardware flow control

UART hardware flow control can be realized by adding nCTS and nRTS signals, that is, the UART hardware module automatically controls the sending and receiving of data according to the high and low levels of nCTS and nRTS, without judging by software. The schematic diagram of hardware flow control between two UART modules is as follows:

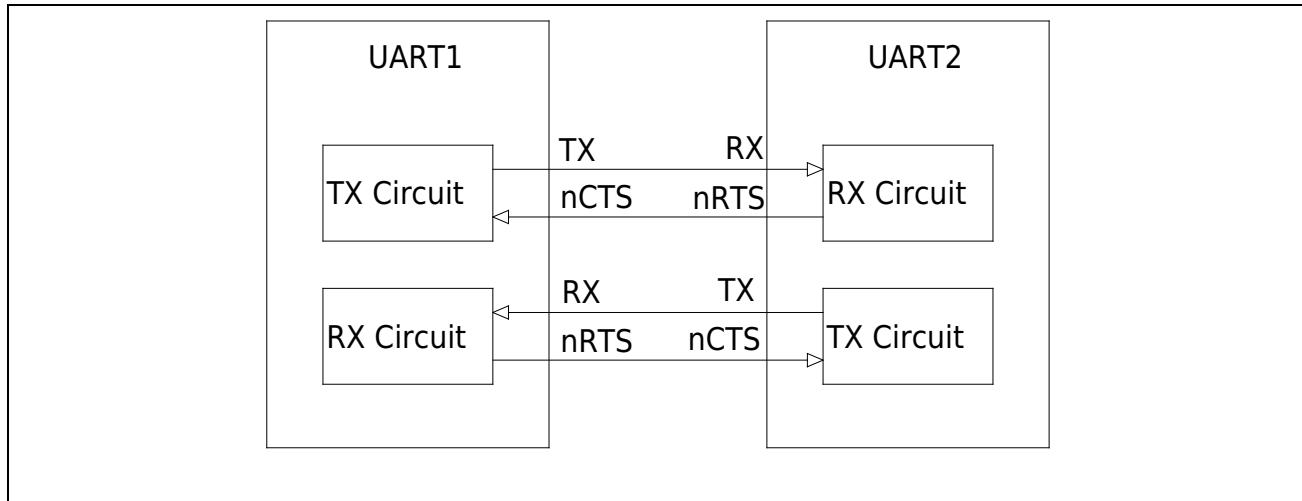

Figure 18-10 UART hardware flow control

■ nRTS flow control

When nRTS flow control is enabled (UARTx_SCON.RTSEN is set to 1):

- nRTS will be asserted (connected low) when the UART receive buffer is empty.
- When the receive buffer is full, nRTS will become invalid (connected to a high level), indicating that the sending process will stop after the end of the current frame.

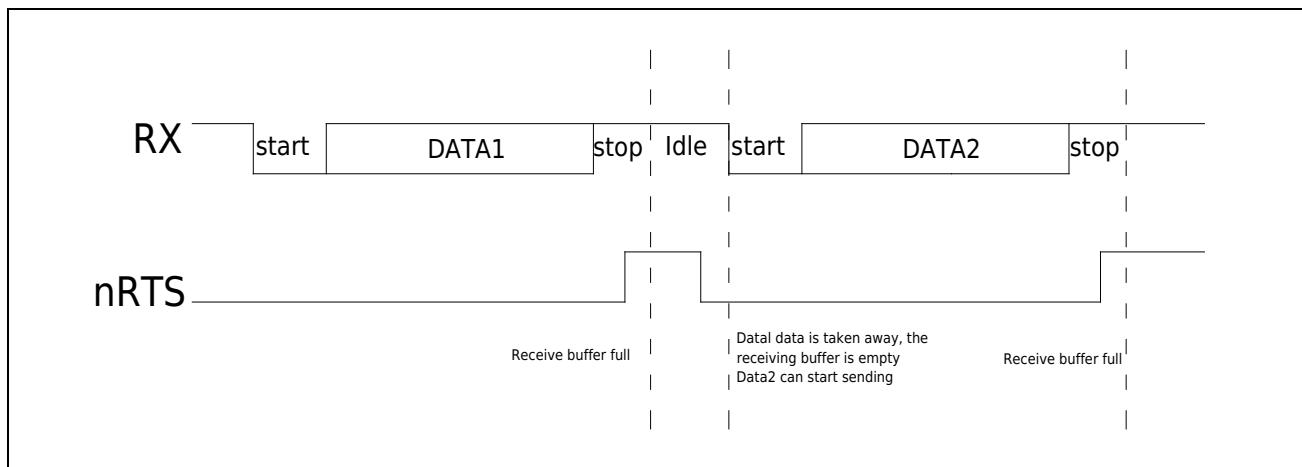

Figure 18-11 nRTS hardware flow control signal

■ CTS flow control

When nCTS flow control is enabled (UARTx_SCON.CTSEN is set to 1), before the UART sends the next frame of data, first judge the high and low levels of nCTS:

- If nCTS is active (connected to low level), the UART sends the next frame of data.
- If nCTS is invalid (connected to high level), UART will suspend sending the next frame of data after the current frame is sent.

When nCTS flow control is enabled, once the nCTS signal is inverted, UARTx_SFLAG.CTSIE will be set to 1 by hardware. If UARTx_SCON.CTSIE is set to 1, an interrupt will be generated, and at the same time, the high and low levels of the nCTS signal will be recorded in the UARTx_SFLAG.CTS flag.

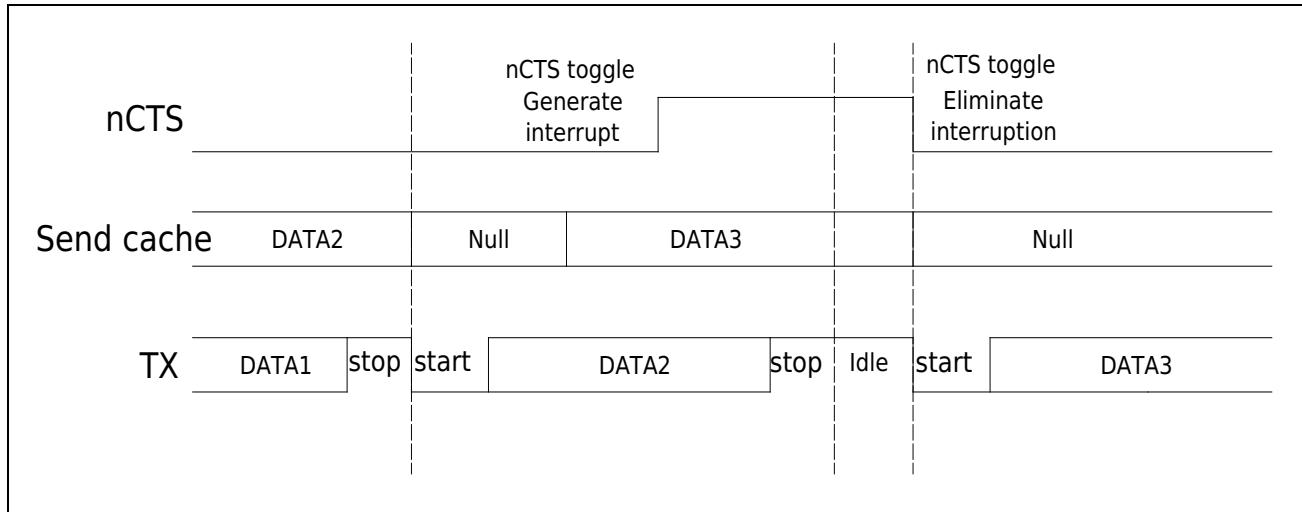

Figure 18-12 nCTS hardware flow control signal

18.3.7 Transceiver buffer

- Receive buffer

The receiving end of the UART module has a frame (8/9-Bit) receiving buffer, which saves the received data frame until the Stop bit of the next frame of data is received and then updates the data frame.

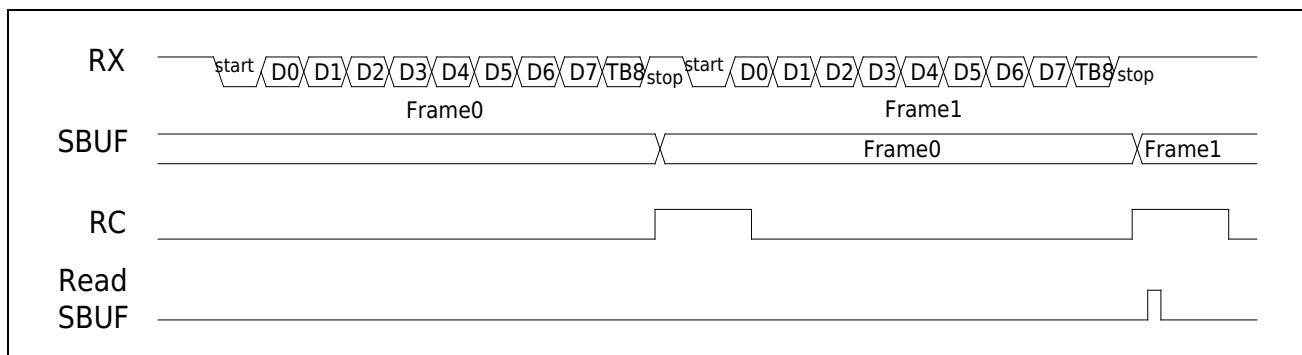

Figure 18-13 Receive buffer

- Send cache

UART module has a frame (8/9-Bit) sending buffer. When the UART is sending the current frame, the software for the next sending data will be written into `UARTx_SBUF`.

When `UARTx_ISR.TXE=0`, it indicates that the current transmit buffer is full, and `UARTx_SBUF` cannot write the next transmit data. Otherwise the data will be discarded by hardware.

When `UARTx_ISR.TXE=1`, it indicates that the current sending buffer is empty, and `UARTx_SBUF` can write the next sending data. After the current data transmission is completed, the hardware automatically loads the data in the sending buffer into the shift register and sends it out.

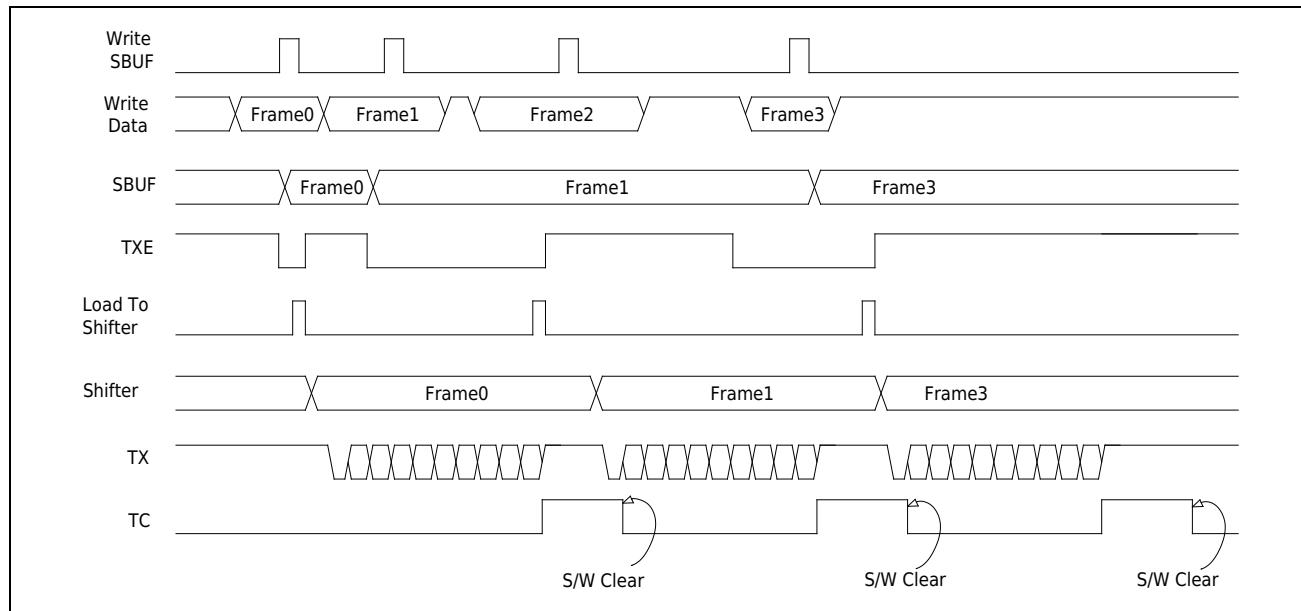

Figure 18-14 Send cache

19 Low Power Synchronous Asynchronous Transceiver (LPUART)

19.1 Introduction

The Low Power Synchronous Asynchronous Receiver (LPUART) is a UART that allows full-duplex UART communication with limited power consumption. Even when the microcontroller is in stop mode with very low power consumption, the LPUART waits for the arrival of UART frames. The LPUART contains all necessary hardware support to enable asynchronous serial communication with minimal power consumption.

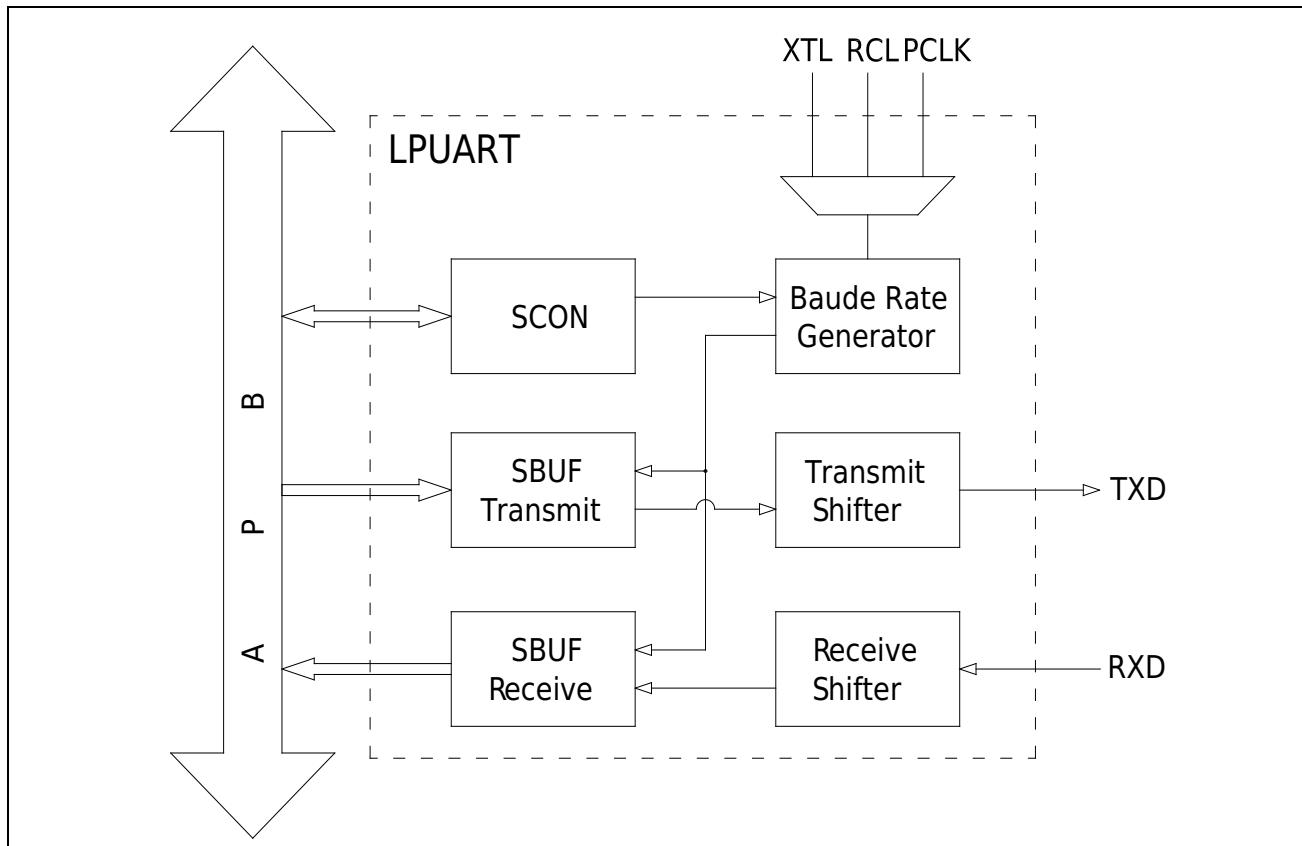

Figure 19-1 Block Diagram

19.2 Main characteristics

LPUART module (LPUART0/1) supports the following basic functions:

- Configuration clock PCLK
- Transmission clock SCLK (SCLK can choose XTL, RCL and PCLK)
- Send and receive data in system low power mode
- Full-duplex transmission, half-duplex transmission, single-wire half-duplex transmission
- Programmable serial communication function
 - Two character lengths: 8 bits, 9 bits
 - Three checkout methods: no checkout, odd checkout, even checkout
 - Three stop lengths: 1 bit, 2 bits, 1.5 bits
- 16-bit baud rate counter
- Multi-machine communication
- Hardware address recognition
- Hardware flow control
- DMAC hardware transmission handshake

19.3 Functional description

19.3.1 Configuration Clock and Transmit Clock

The LPUART module has two clocks: configuration clock PCLK and transfer clock SCLK.

- Configure clock

The configuration clock (PCLK) is used for register configuration of the LPUART module by the system APB bus, and the configuration clock is fixed as the APB bus clock PCLK. When the system enters Deep Sleep (DeepSleep) mode, the PCLK clock will stop.

- Transmission clock

The transmission clock (SCLK) is used for LPUART data transceiver logic work, and the external low-speed crystal oscillator clock (XTL), the internal low-speed RC clock (RCL) and the PCLK clock can be selected.

When the system enters Deep Sleep (DeepSleep) mode, if SCLK selects external low-speed crystal oscillator clock (XTL) or internal low-speed RC clock (RCL). LPUART can still perform normal data transmission and reception without being affected by the system's deep sleep (DeepSleep) mode.

19.3.2 Operating mode

LPUART supports multiple working modes: synchronous half-duplex mode, asynchronous full-duplex mode, and single-wire half-duplex mode. Through the combination of LPUARTx_SCON.SM and LPUARTx_SCON.HDSEL, various working modes can be configured.

19.3.2.1 Mode0~Mode3 function comparison

Configure LPUARTx_SCON.SM to select different transmission modes: Mode0~Mode3. The main function comparison of these four working modes is shown in the table below:

Table 19-1 Mode0/1/2/3 Data Structure

Operating mode		Transmission bit width	Data composition	Baud rate
Mode0	synchronous mode Half duplex	8-Bit	Data(8bit)	$\text{BaudRate} = \frac{f_{\text{sclk}}}{12}$
Mode1	Asynchronous mode Full duplex	10-Bit	Start(1bit) + Data(8bit) + Stop (1~2bit)	$\text{BaudRate} = \frac{f_{\text{sclk}}}{\text{OVER} * \text{SCNT}}$
Mode2	Asynchronous mode Full duplex	11-Bit	Start (1bit) + Data(8bit) + B8(1bit) + Stop (1~2bit)	$\text{BaudRate} = \frac{f_{\text{sclk}}}{\text{OVER}}$
Mode3	Asynchronous mode Full duplex	11-Bit	Start (1bit) + Data(8bit) + B8(1bit) + Stop (1~2bit)	$\text{BaudRate} = \frac{f_{\text{sclk}}}{\text{OVER} * \text{SCNT}}$

Note:

- Mode0 can only be used as a host to send LPUART synchronous shift clock, and cannot be used as a slave to receive externally input LPUART synchronous shift clock;
- f_{sclk} is the clock frequency of SCLK;
- The definition of OVER is detailed in LPUARTx_SCON;
- LPUARTx_SCNT for the definition of SCNT;
- The B8 data bit is special and has different meanings in different applications, please refer to the following table:

Table 19-2 B8 Data Meaning

Application Scenario	LPUARTx_SCON.ADRDET	LPUARTx_SCON.B8CONT[1:0]	B8 Data Meaning
Parity	--	01/10	When receiving, B8 is the parity bit of the received 8-Bit data; When sending, B8 is the parity bit of the sent 8-Bit data;
Multi-machine communication	1	--	B8=1, it means that it is currently an address frame; B8=0, it means the current data frame;
Other	0	00/11	Received / sent DATA[8]

Note:

- When the multi-machine communication mode is turned on, the parity check of the received data is automatically closed; the parity check of the sent data is still controlled by B8CONT.

19.3.2.2 Mode0 data sending and receiving instructions

When sending data, clear the LPUARTx_SCON.REN bit and write the data into the LPUARTx_SBUF register. At this time, the sending data will be output from RXD (low bit first, high bit later), and the synchronous shift clock will be output from TXD.

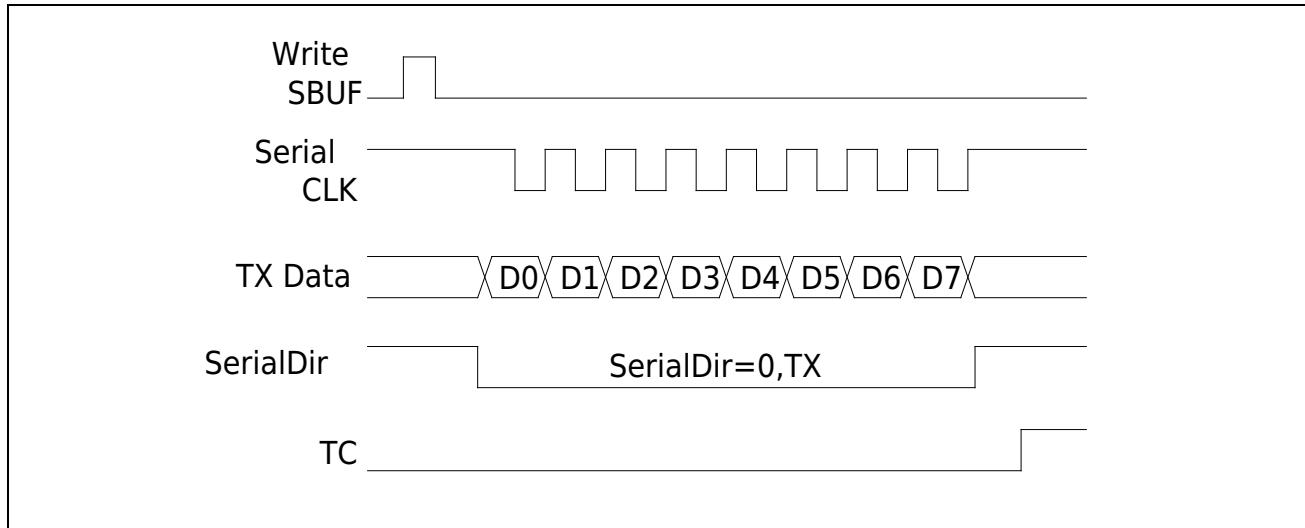

Figure 19-2 Mode0 sending data

When receiving data, set the LPUARTx_SCON.REN bit and clear the LPUARTx_ISR.RC bit. When reception is complete, data can be read from the LPUARTx_SBUF register. At this time, the received data is input from RXD (low bit first, high bit later), and the synchronous shift clock is output from TXD.

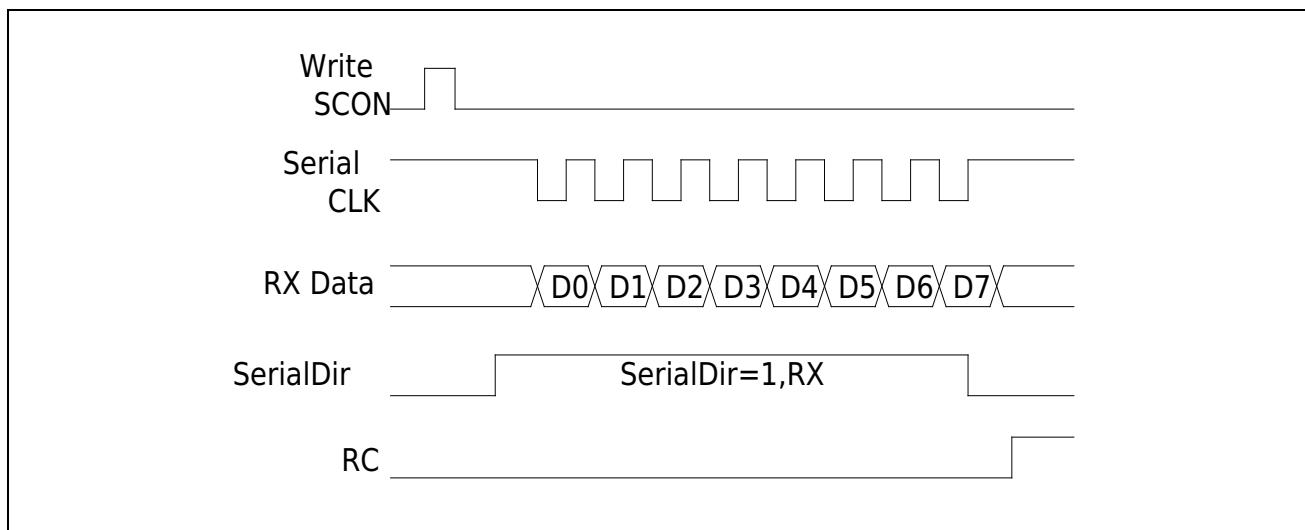

Figure 19-3 Mode0 receiving data

19.3.2.3 Mode1 data sending and receiving instructions

When sending data, it has nothing to do with the value of LPUARTx_SCON.REN, write the sent data into the LPUARTx_SBUF register, and the data will be shifted out from TXD (low bit first, high bit later).

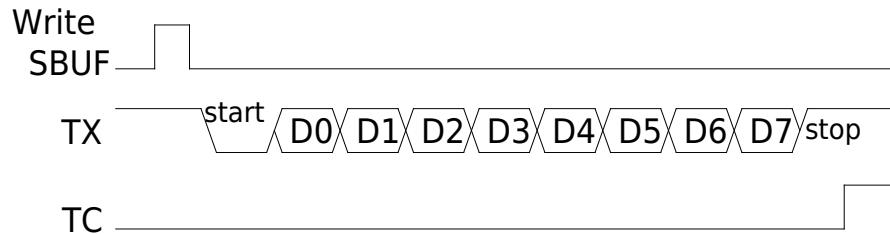

Figure 19-4 Mode1 sending data

When receiving data, set the LPUARTx_SCON.REN bit to 1 and clear the LPUARTx_ISR.RC bit to 0. Start to receive data on RXD (low bit first, high bit later), when the reception is complete, it can be read from the LPUARTx_SBUF register.

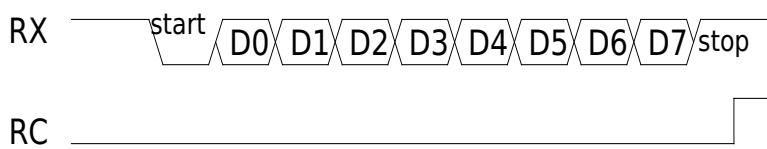

Figure 19-5 Mode1 receiving data

19.3.2.4 Mode2 data sending and receiving instructions

When sending data, it has nothing to do with the value of LPUARTx_SCON.REN, write the sent data into the LPUARTx_SBUF register, and the data will be shifted out from TXD (low bit first, high bit later).

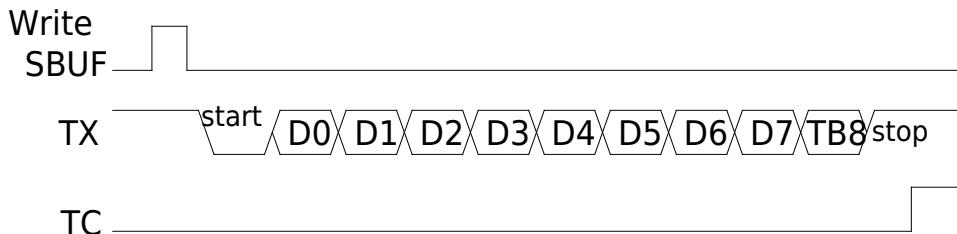

Figure 19-6 Mode2 sending data

When receiving data, it is necessary to set the LPUARTx_SCON.REN bit to 1, and clear the LPUARTx_ISR.RC bit to 0. Start to receive the data on RXD (low bit first, high bit later), when the reception is complete, it can be read from the LPUARTx_SBUF register.

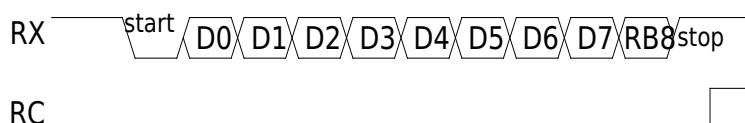

Figure 19-7 Mode2 receiving data

19.3.2.5 Mode3 data sending and receiving instructions

When sending data, it has nothing to do with the value of LPUARTx_SCON.REN, write the sent data into the LPUARTx_SBUF register, and the data will be shifted out from TXD (low bit first, high bit later).

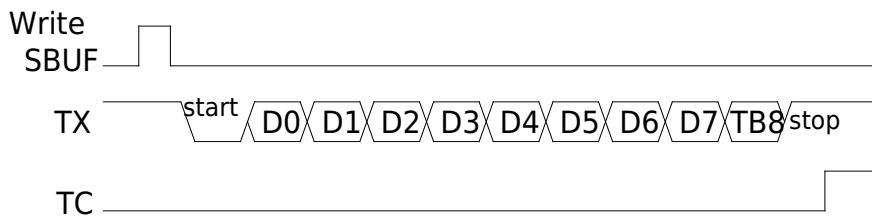

Figure 19-8 Mode3 sending data

When receiving data, set the LPUARTx_SCON.REN bit to 1 and clear the LPUARTx_ISR.RC bit to 0. Start to receive data on RXD (low bit first, high bit later), when the reception is complete, it can be read from the LPUARTx_SBUF register.

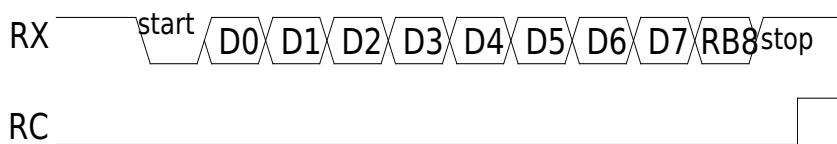

Figure 19-9 Mode3 receiving data

19.3.2.6 Description of single-wire half-duplex data transmission and reception

When LPUARTx_SCON.HDSEL=1'b1, it can enter single-wire half-duplex transmission mode:

- The TX and RX signal lines are connected inside the module.
- The RX signal is no longer used, and the received and sent data are all completed through the TX signal. TX signal is done by hardware logic without software control.
- When the transmit buffer is empty, the TX signal is always input (receive state). Once a data is filled into the transmit buffer, the TX signal becomes output (transmit status). When the transmission is complete, the transmit buffer becomes empty and the TX signal returns to input (receive state).
- When there is no data transmission, the TXD pin is always in the input state. The user program needs to configure this pin as an open-drain output and connect an external pull-up resistor.

Note:

1. Even if the module is in the process of receiving, as long as the sending buffer is filled with data, the TX signal will immediately become output (transmitting state). The receiving process will be interrupted and a wrong received data will be obtained.
2. single-line half-duplex mode and Mode0 mode:
The same: both use a signal to time-division multiplex to complete data transmission and

reception.

Different: Mode0 is synchronous transmission, with synchronous clock. The single-wire half-duplex mode is asynchronous transmission, and all baud rate calculations still follow the baud rate formula of Mode1~Mode3, only the transceiver function is multiplexed on the TX signal.

19.3.3 Baud rate generation

Mode0~Mode3 are different, as shown below for details.

$$\text{Mode0 baud rate generation formula: } \text{BaudRate} = \frac{f_{SCLK}}{12}$$

$$\text{Mode1 baud rate generation formula: } \text{BaudRate} = \frac{f_{SCLK}}{\text{OVER} * \text{SCNT}}$$

$$\text{Mode2 baud rate generation formula: } \text{BaudRate} = \frac{f_{SCLK}}{\text{OVER}}$$

$$\text{Mode3 baud rate generation formula: } \text{BaudRate} = \frac{f_{SCLK}}{\text{OVER} * \text{SCNT}}$$

Note:

- f_{SCLK} represents the frequency of the current SCLK;
- The definition of OVER is detailed in LPUARTx_SCON;
- LPUARTx_SCNT for the definition of SCNT.

19.3.4 Frame error detection

When working in Mode1/2/3, LPUART has a frame error detection function. If the stop bit is not recognized within the expected time when receiving data, resulting in synchronization failure or excessive noise, a frame error will be detected. LPUARTx_ISR.FE is set to 1 when a framing error is detected. LPUARTx_ISR.FE should be cleared by software in time.

19.3.5 Multi-machine communication

When working in Mode2/3, set the LPUARTx_SCON.ADRDET bit to "1" to enable the multi-device communication function.

The host can use LPUARTx_SBUF[8] to distinguish whether the current sending frame is an address frame (LPUARTx_SBUF[8]=1) or a data frame (LPUARTx_SBUF[8]=0).

- When it is a data frame, the frame data will not be stored in the LPUARTx_SBUF register of the slave, and the slave will not generate a receive interrupt.
- When it is an address frame, since the automatic address recognition function in the multi-machine communication has been turned on, the slave can detect whether the received address matches its own address.
 - If the address matches, the slave will set "1" to LPUARTx_ISR.RC, set "1" to LPUARTx_SBUF[8], and store the address frame into the LPUARTx_SBUF register at the same time. LPUARTx_SBUF[8]=1 and LPUARTx_ISR.RC=1, the slave software clears the LPUARTx_SCON.ADEDET bit to "0" and accepts the data frame.
 - If the address does not match, it means that the master is not addressing the slave, the slave hardware keeps LPUARTx_SBUF[8] and LPUARTx_ISR.RC as "0", the software keeps the LPUARTx_SCON.ADRDET bit as "1", and the slave continues to be in the address monitoring state.

Note:

- If necessary, the multi-device communication bit can also be turned on in Mode1, and the TB8 bit is replaced by the stop bit. When the slave receives a matching address frame and a valid stop bit, LPUARTx_ISR.RC will be set to "1".

19.3.5.1 Given address

LPUARTx_SADDR register of the LPUART device is used to indicate the given address of its own device. The LPUARTx_SADEN register is an address mask. When a certain bit of LPUARTx_SADEN is "0", it can be used to define irrelevant bits in the address and does not participate in address matching. These don't care bits increase addressing flexibility, allowing the master to address one or more slave devices simultaneously.

Note: If a unique matching address needs to be given, the LPUARTx_SADEN register must be set to 8'hFF. The given address formula looks like this:

GivenAddr=SADDR&SADEN

19.3.5.2 Broadcast address

The broadcast address is used to address all slave devices at the same time, and the general broadcast address is 8'hFF.

BroadCastAddr=SADDR|SADEN

19.3.5.3 Example

LPUARTx_SADDR and LPUARTx_SADEN of a slave is as follows:

SADDR: 8'b01101001

SADEN: 8'b11111011

Then its given address and broadcast address are as follows:

Given: 8'b01101x01

Broadcast: 8'b11111x11

It can be seen that the master can use four addresses to address the slave, namely:

8'b01101001 and 8'b01101101 (given address)

8'b11111011 and 8'b11111111 (broadcast address).

19.3.6 DMAC hardware handshake

The LPUART module supports the hardware handshaking logic of the DMAC.

- Setting LPUARTx_SCON.DMACTXEN to 1 can turn on the DMAC hardware handshaking logic of LPUART TX. When the send buffer is empty, the LPUART will send a data transfer request TX REQ to the DMAC. the DMAC receives this signal, it transfers the sending data of one frame from the DMAC source address to LPUARTx_SBUF. The above steps are repeated until all the data lengths configured in the DMAC are transferred.
- Setting LPUARTx_SCON.DMACRXEN to 1 can turn on the DMAC hardware handshaking logic of LPUART RX. When a frame is received, LPUART will send a data transfer request RX REQ to DMAC. When DMAC receives this signal, it transfers the received data from LPUARTx_SBUF to the target address of DMAC. The above steps are repeated until all the data lengths configured in the DMAC are transferred.

19.3.7 Hardware flow control

LPUART hardware flow control can be realized by adding nCTS and nRTS signals, that is, the LPUART hardware module automatically controls the sending and receiving of data according to the high and low levels of nCTS and nRTS, without judging by software. The hardware flow control diagram between two LPUART modules is as follows:

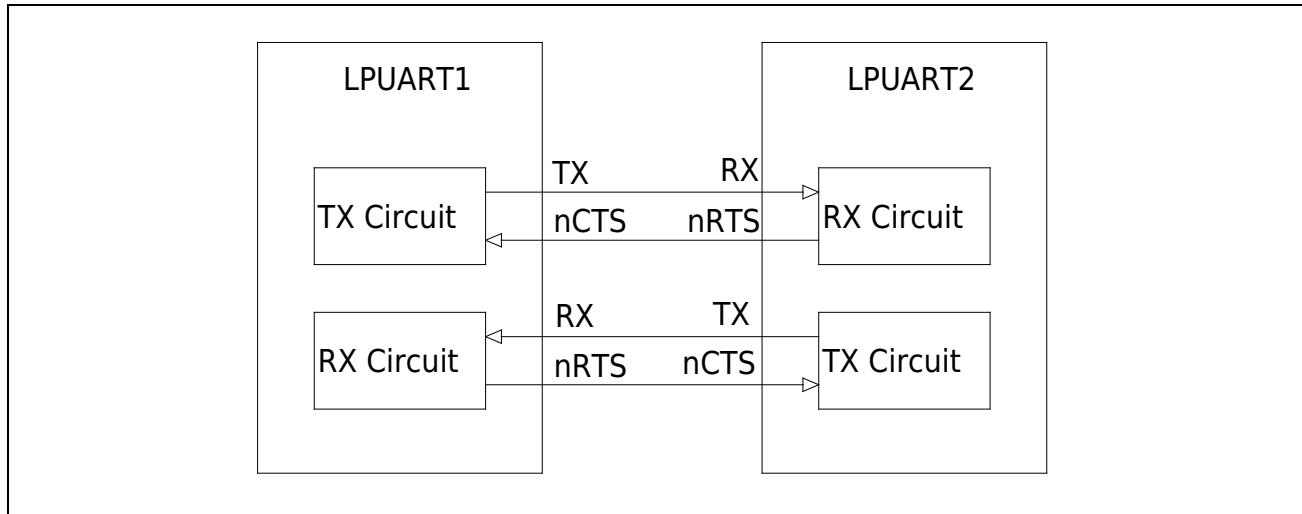

Figure 19-10 LPUART hardware flow control

■ nRTS flow control

When nRTS flow control is enabled (LPUARTx_SCON.RTSEN is set to 1):

- When the LPUART receive buffer is empty, nRTS will be asserted (connected to low level).
- When the receive buffer is full, nRTS will become invalid (connected to a high level), indicating that the sending process will stop after the end of the current frame.

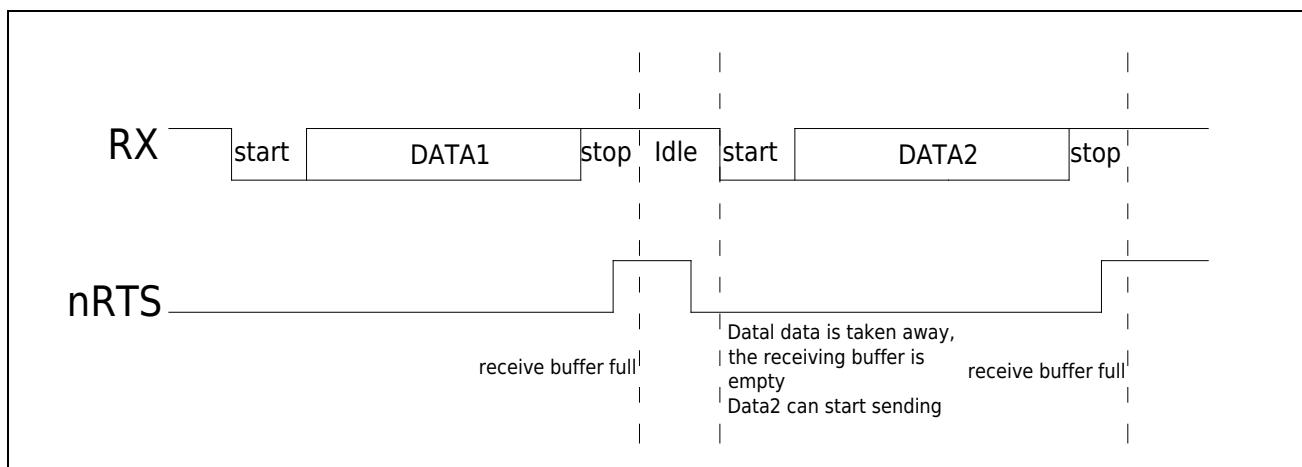

Figure 19-11 nRTS hardware flow control signal

■ CTS flow control

When nCTS flow control is enabled (LPUARTx_SCON.CTSEN is set to 1), before LPUART sends the next frame of data, first judge the high and low level of nCTS:

- If nCTS is active (connected to low level), then LPUART sends the next frame of data.
- If nCTS is invalid (connected to high level), then LPUART will suspend the transmission of the next frame after the current frame transmission is completed

When nCTS flow control is enabled, once the nCTS signal is inverted, LPUARTx_SFLAG.CTSIF will be set to 1 by hardware. If LPUARTx_SCON.CTSIE is set, an interrupt will be generated. At the same time, the high and low levels of the nCTS signal will be recorded in the LPUARTx_SFLAG.CTS flag.

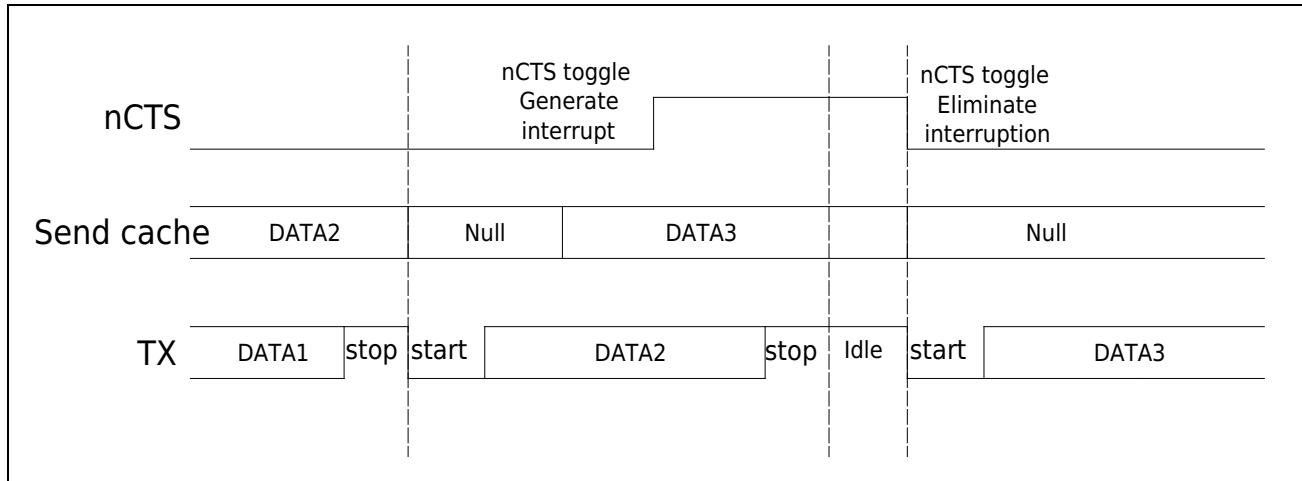

Figure 19-12 nCTS hardware flow control signal

19.3.8 Transceiver buffer

- Receive buffer

The receiving end of the LPUART module has a frame (8/9-Bit) receiving buffer, that is, the received data frame is kept until the Stop bit of the next frame of data is received to update the data frame.

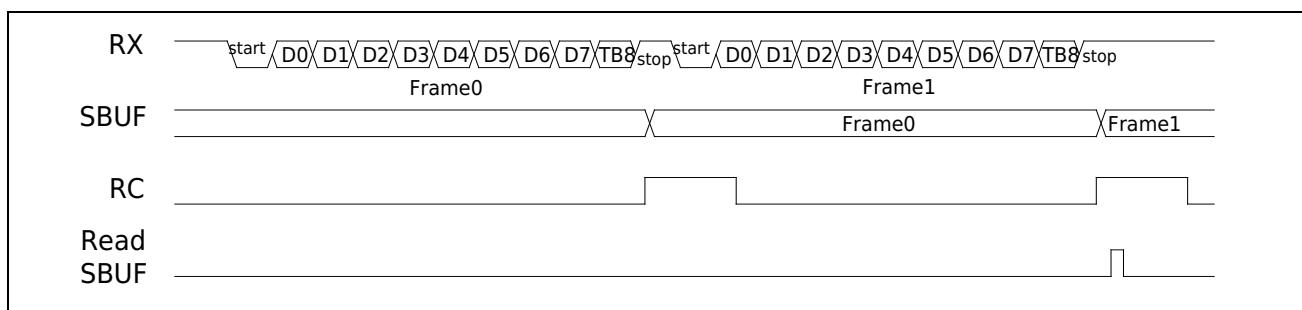

Figure 19-13 Receive buffer

- Send cache

LPUART module has a frame (8/9-Bit) sending buffer. When the LPUART is sending the current frame, the software writes the next sending data to LPUARTx_SBUF.

When LPUARTx_ISR.TXE=0, it indicates that the current transmit buffer is full, and the next transmit data cannot be written into LPUARTx_SBUF. Otherwise the data will be discarded by hardware.

When LPUARTx_ISR.TXE=1, it indicates that the current sending buffer is empty, and LPUARTx_SBUF can write the next sending data. After the current data transmission is completed, the hardware automatically loads the data in the sending buffer into the shift register and sends it out.

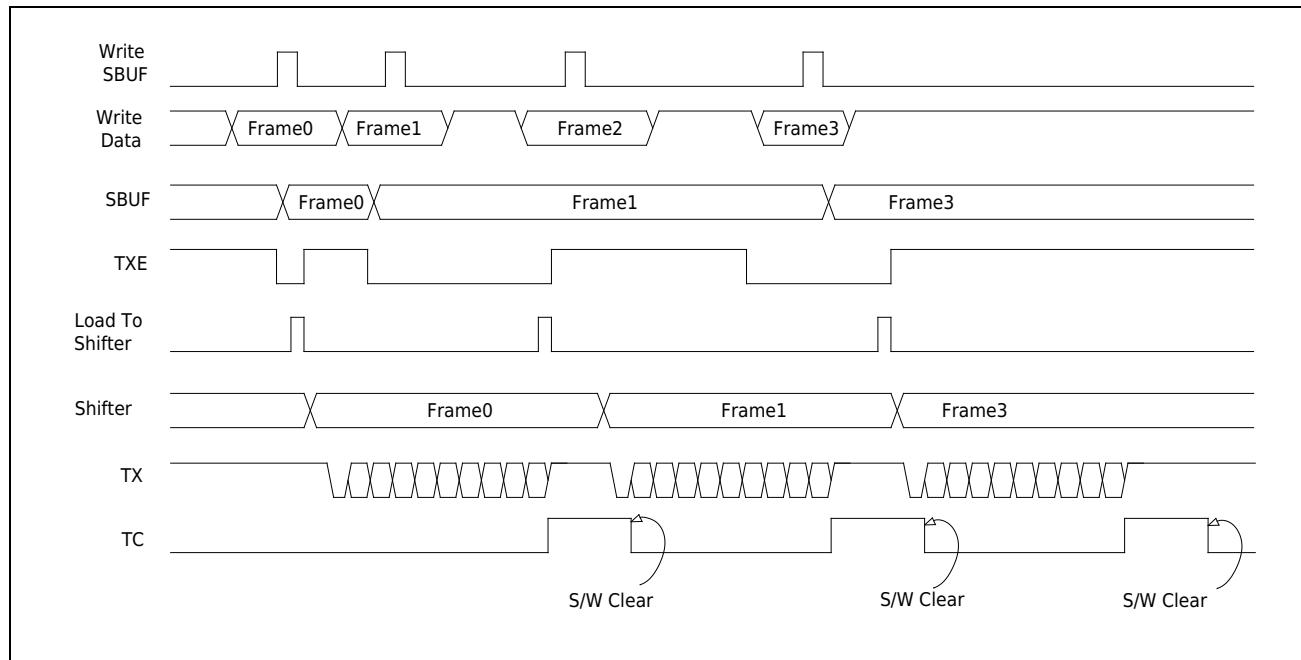

Figure 19-14 Send cache

20 Cyclic redundancy check (CRC)

20.1 Overview

A cyclic redundancy check (CRC) calculation unit takes a data stream or data block as input and generates an output number under the control of a generator polynomial. This output number is often used to verify the correctness and integrity of data transmission or storage. This module supports calculating CRC value and checking CRC value.

20.2 Main characteristics

- One implementation standard: ISO/IEC13239
- Two encoding methods: CRC-16, CRC-32
- Three write bit widths: 8bit, 16bit, 32bit
- Two working modes: CRC encoding mode, CRC check mode
- CRC-16 polynomial: $x^{16} + x^{12} + x^5 + 1$
- CRC-32 polynomial: $x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$

20.3 Functional description

20.3.1 Operating mode

This module supports two working modes: CRC encoding mode and CRC checking mode.

The CRC encoding mode is to input a certain amount of raw data to the CRC module and obtain the output value (CRC_RESULT) generated by the CRC module. The CRC check mode is to point to the CRC module to input a certain amount of original data + CRC check value, and verify whether the original data matches the CRC check value (CRC_CR.FLAG).

20.3.2 Encoding

This module supports two encoding methods CRC-16 and CRC-32, and the calculation results are 16 bits and 32 bits respectively. Configure the encoding method to be used through CRC_CR.CR.

CRC-16 polynomial: $x^{16} + x^{12} + x^5 + 1$.

CRC-32 polynomial: $x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$.

20.3.3 Write bit width

This module supports three write bit widths: 8bit, 16bit, 32bit. The writing of different bit widths needs to comply with the principle of "consistent bit width, low first and then high", that is, "every time data is written, it must be written into a register equal to the effective data bit width of this time, and the lower bit Data is written before higher bit data".

The following shows how the same sequence of data is written using three bit widths, and the output results are the same.

- 8bit bit width write: 0x00, 0x11, 0x22, 0x33, 0x44, 0x55, 0x66, 0x77
- 16bit bit width write: 0x1100, 0x3322, 0x5544, 0x7766
- 32bit bit width write: 0x33221100, 0x77665544

20.4 Programming example

20.4.1 CRC-16 encoding mode

- Step 1: Write 0x00 to CRC_CR.CR to select CRC-16.
- Step 2: Write 0xFFFF to CRC_RESULT to initialize CRC calculation.
- Step 3: Write the original data to be encoded into the CRC_DATA register in sequence, and the write bit width can be selected from 8bit, 16bit, and 32bit.
- Step 4: Read CRC_RESULT[15:0] to get the CRC value.

20.4.2 CRC-16 check mode

- Step 1: Write 0x00 to CRC_CR.CR to select CRC-16.
- Step 2: Write 0xFFFF to CRC_RESULT to initialize CRC calculation.
- Step 3: Write the encoded data sequence into the CRC_DATA register in sequence, and the write bit width can be selected from 8bit, 16bit, and 32bit.
- Step 4: Determine whether the encoded data sequence has been tampered with according to the value of CRC_CR.FLAG.

20.4.3 CRC-32 encoding mode

- Step 5: Write 0x01 to CRC_CR.CR to select CRC-32.
- Step 6: Write 0xFFFFFFFF to CRC_RESULT to initialize CRC calculation.
- Step 7: Write the original data to be encoded into the CRC_DATA register in sequence, and the write bit width can be selected from 8bit, 16bit, and 32bit.
- Step 8: Read CRC_RESULT[31:0] to get the CRC value.

20.4.4 CRC-32 check mode

- Step 5: Write 0x01 to CRC_CR.CR to select CRC-32.
- Step 6: Write 0xFFFFFFFF to CRC_RESULT to initialize CRC calculation.
- Step 7: Write the encoded data sequence into the CRC_DATA register in sequence, and the write bit width can be selected from 8bit, 16bit, and 32bit.

Step 8: Determine whether the encoded data sequence has been tampered with according to the value of CRC_CR.FLAG.

21 True random number generator (TRNG)

21.1 Overview

The true random number module generates 64-bit true random numbers.

21.2 Functional block diagram

The following shows the data flow of the TRNG module:

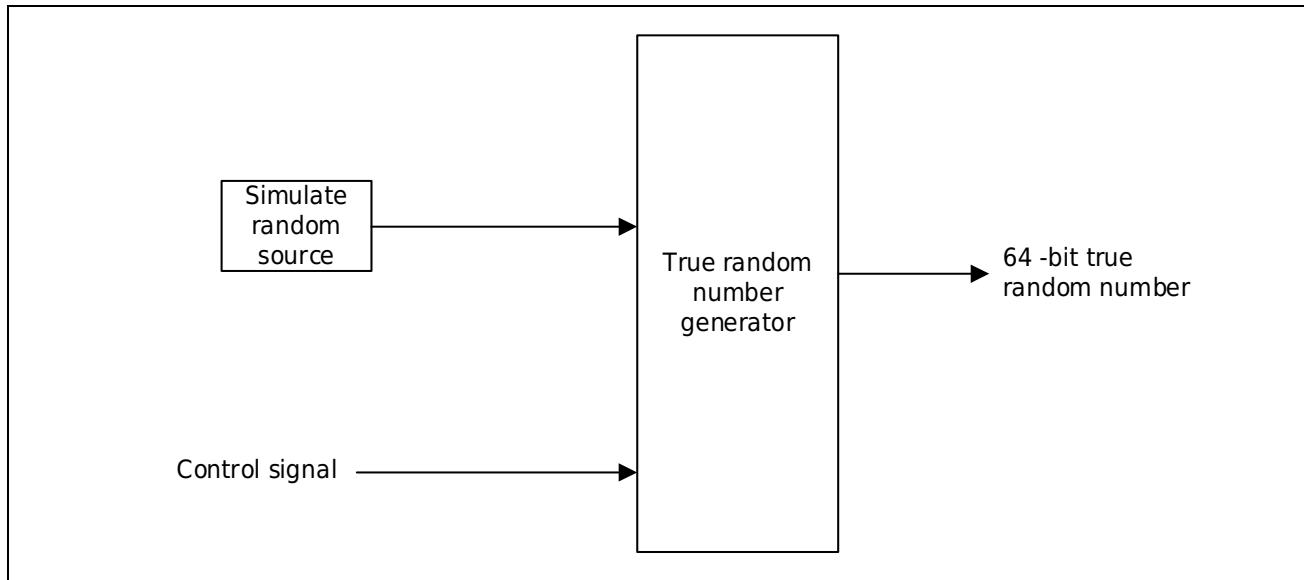

Figure 21-1 TRNG data flow

21.3 Functional description

This module uses an internal analog random source, which can generate 64bits true random numbers every time it is started. In addition, software configuration can be performed on the way of true random number generation. For details, please refer to the register description chapter. The generated 64-bit true random numbers are stored in DATA0 and DATA1 registers respectively.

21.4 Register

Base address: 0x4000 4C00

Register	Offset address	Description
TRNG_CR	0x00	Control register
TRNG_MODE	0x04	Mode register
TRNG_DATA0	0x0C	Data register 0
TRNG_DATA1	0x10	Data register 1

21.4.1 Control Register (TRNG_CR)

Offset address: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31:0	DATA1	32-bit random number when reading this register

21.5 Basic operation of the software

21.5.1 The operation process of generating 64bits true random number (the first time after power-on)

To generate a 64bits true random number for the first time after power-on, the following operations are required:

Step1: Turn on the random source circuit: write "1" to Bit0 (TRNG_CR.TRNGcir_En) of the true random number control register, start the random source circuit, and start outputting serial true random numbers.

Step2: Choose to reload the initial value: Set Bit0 (TRNG_MODE.TRNG_LOAD) of the true random number mode register to "1", so that the initial value of the newly generated true random number is obtained from a random source.

Step3: Select the direct feedback method of PRNG64: set Bit1 (TRNG_MODE.TRNG_FDBK) of the true random number mode register to "1", XOR the feedback signal with the random source and input it into the PRNG.

Step4: Select the number of shifts of PRNG64: set Bit4 - Bit2 (TRNG_MODE.TRNG_CNT) of the true random number mode register to "110", and select 256 shifts.

Step5: Generating a true random number: the software writes "1" into Bit1 of the true random number control register (TRNG_CR.TRNG_RUN), and the hardware operates according to the true random number generation configuration. After the operation is completed, the hardware automatically clears Bit1 to "0".

Step6: Choose not to reload the initial value: Set Bit0 (TRNGModeReg.TRNG_Load) of the true random number mode register to "0".

Step7: Select the direct feedback method of PRNG64: set Bit1 (TRNG_MODE.TRNG_FDBK) of the true random number mode register to "0", and directly input the feedback signal into the PRNG.

Step8: Select the number of shifts for PRNG64: set Bit4 - Bit2 (TRNG_MODE.TRNG_CNT) of the true random number mode register to "100", and select 64 shifts.

Step9: Generating a true random number: the software writes "1" into Bit1 of the true random number control register (TRNG_CR.TRNG_RUN), and the hardware operates according to the true random number generation configuration. After the operation is completed, the hardware automatically clears Bit1 to "0".

Step10: Read the true random number: After the software inquires that the Bit1 (TRNG_CR.TRNG_RUN) of the true random number control register has changed to "0", it

reads the true random number data register 0 (TRNG_DATA0) and the true random number data register 1 (TRNG_DATA1) to get 64Bits true random number.

Step11: After completing the generation of true random numbers, it is recommended to turn off the random source circuit to save power consumption: write "0" to Bit0 (TRNG_CR.TRNGcir_En) of the true random number control register to turn off the random source circuit.

21.5.2 Generating 64bits true random number (not generated for the first time after power-on)

A 64bits true random number for the first time without power-on, the following operations are required:

Step1: Turn on the random source circuit: write "1" to Bit0 (TRNG_CR.TRNGcir_En) of the true random number control register, start the random source circuit, and start outputting serial true random numbers.

Step2: Choose not to reload the initial value: Set Bit0 (TRNG_MODE.TRNG_LOAD) of the true random number mode register to "0".

Step3: Select the direct feedback method of PRNG64: set Bit1 (TRNG_MODE.TRNG_FDBK) of the true random number mode register to "1", and input the feedback signal into the PRNG after XORing with the random source.

Step4: Select the number of shifts for PRNG64: set Bit4 - Bit2 (TRNG_MODE.TRNG_CNT) of the true random number mode register to "110", and select 256 shifts.

Step5: Generating a true random number: the software writes "1" into Bit1 of the true random number control register (TRNG_CR.TRNG_RUN), and the hardware operates according to the true random number generation configuration. After the operation is completed, the hardware automatically clears Bit1 to "0".

Step6: Select the direct feedback method of PRNG64: set Bit1 (TRNG_MODE.TRNG_FDBK) of the true random number mode register to "0", and directly input the feedback signal into the PRNG.

Step7: Select the number of shifts for PRNG64: set Bit4 - Bit2 (TRNG_MODE.TRNG_CNT) of the true random number mode register to "100", and select 64 shifts.

Step8: Read the true random number: After the software inquires that the Bit1 (TRNG_CR.TRNG_RUN) of the true random number control register has changed to "0", it reads the true random number data register 0 (TRNG_Data0) and the true random number data register 1 (TRNG_Data1), get 64Bits true random number.

If it is necessary to continue to generate new true random numbers, then go back to Step2 until the requirements are met.

Step9: After completing the generation of true random numbers, it is recommended to turn off the random source circuit to save power consumption: write "0" to Bit0 (TRNG_CR.TRNGcir_En) of the true random number control register to turn off the random source circuit.

22 Advanced Encryption Standard Module (AES)

22.1 Function definition

22.1.1 AES algorithm

AES (The Advanced Encryption Standard) is a new data encryption standard officially announced by the National Institute of Standards and Technology (NIST) on October 2, 2000.

AES is fixed at 128 bits, while the key length supports 128, 192 and 256 bits. For encryption, the input is a plaintext block and a key, and the output is a ciphertext block; for decryption, the input is a ciphertext block and a key, and the output is a plaintext block. This process is shown in Figure 22-1:

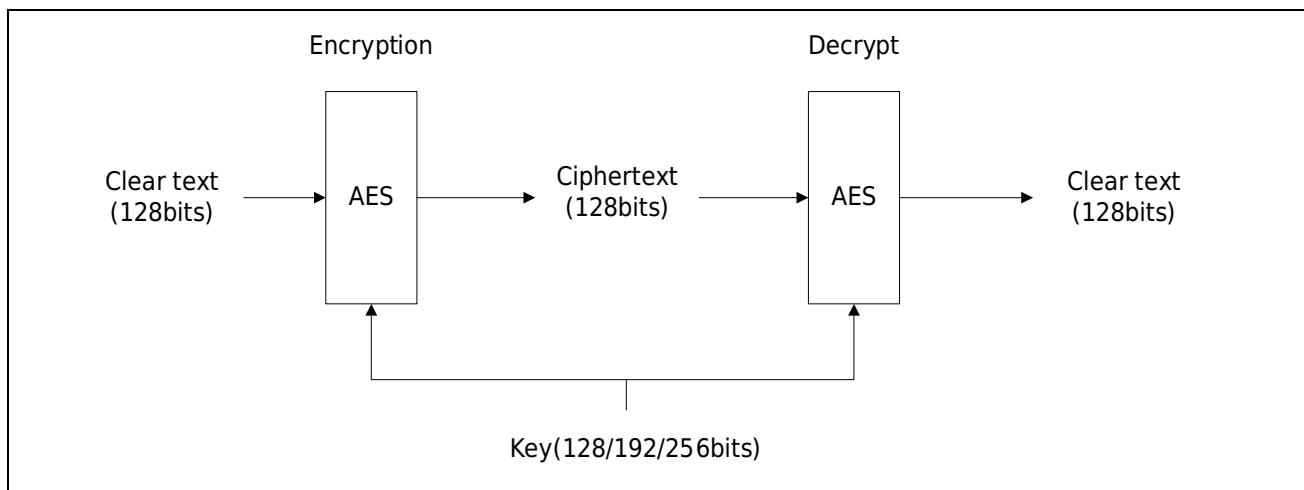

Figure 22-1 Schematic Diagram of AES Encryption and Decryption

The basic unit processed by the AES algorithm is the byte. The 128-bit information is divided into 16 bytes, which are copied into a 4×4 matrix in order, which is called the state (state). All transformations of AES are transformations based on the state matrix, the intermediate results of the calculation are stored on this matrix.

AES is a key iterative block cipher that involves round-robin repetition of state. AES consists of four operations: SubBytes, ShiftRows, MixColumns, AddRoundKey. Among them, SubBytes includes finding the modular inverse of each byte in GF(2⁸) and an affine transformation; ShiftRows is a byte transposition, which cyclically shifts the rows in the state according to different offsets; MixColumns linearly transforms each column of the state; AddRoundKey performs a bit-by-bit XOR operation between each byte in the state and the round key. The encryption process of AES is shown in Figure 22-2:

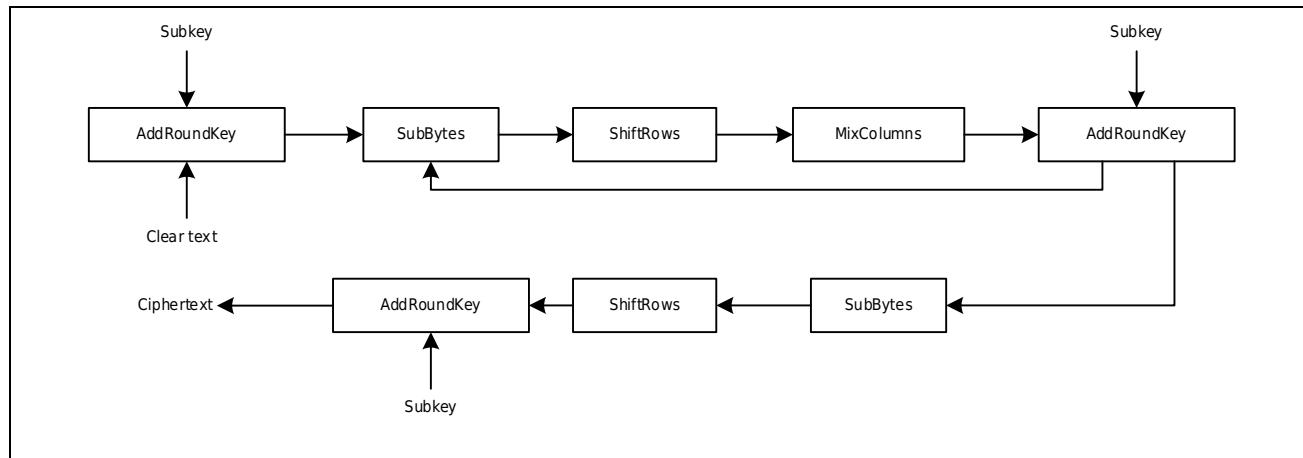

Figure 22-2 AES Encryption Flowchart

The subkey used in the figure needs to be expanded from the initial key, and the key expansion process and encryption process are carried out synchronously.

Since the plaintext is fixed at 128 bits, the number of rounds the encryption process runs depends on the length of the key. For example, when the key is 128 bits, the number of running rounds is 10; when the key is 192 bits, the number of running rounds is 12; when the key is 256 bits, the number of running rounds is 14 rounds. Except for the lack of MixColumns transformation in the last round, the rest of the rounds perform a complete round transformation operation.

The decryption process is different from the encryption process. First, the expansion of all keys must be completed, and the decryption process is used backwards from the last round of expansion; then the four operations of round transformation become the corresponding inverse operations: InvSubBytes, InvShiftRows, InvMixColumns, AddRoundKey. The modular inverse operation in InvSubBytes is still maintained, but the affine transformation is changed to inverse transformation; InvShiftRows and InvMixColumns become corresponding inverse transformations; AddRoundKey remains unchanged.

The calling order of the four operations in the round transformation of the direct decryption process is: InvShiftRows, InvSubBytes, AddRoundKey, InvMixColumns, which is inconsistent with the calling order of the encryption process, but the key used is consistent with the encryption process; the round transformation of the equivalent decryption process is for four The calling order of the operations is: InvSubBytes, InvShiftRows, InvMixColumns, AddRoundKey, which is exactly the same as the calling order of the encryption process, except that the subkeys of each round need to perform InvMixColumns operations.

For the detailed algorithm expression, please refer to the standard " FIPS PUB 197 ".

22.1.2 AES module function description

- Execute the encryption process and decryption process of the AES algorithm standard, and its execution results fully comply with the description of the algorithm principle in " FIPS PUB 197 ";
- 128, 192 and 256 -bit keys are supported.

22.2Module register description

AES base address 0x40021400

Table 22-1 Register List

Register	Offset address	Description
AES_CR	0x00 或 0x40	control register
AES_Data	0x10~0x1C	Data register
AES_Key	0x20~0x3C	key register

22.2.1 Control Register (AES_CR)

Offset address: 0x00 or 0x40

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															

Bit	Symbol	Description
31:5	Reserved	Reserved bit, read as 0
4:3	Keysize	2'b00: key length is 128 bits 2'b01: key length is 192 bits 2'b10: key length is 256 bits 2'b11: key length is 128 bits
2	Reserved	Reserved bit, read as 0
1	Mode	0: encryption operation 1: Decryption operation
0	Start	0: The operation of this module is completed or has not been started 1: Start this module for calculation

Note:

1. The AES_CR.Start bit is: after the software writes 1 to this bit, the module will start running. After this operation, the hardware of this module will automatically clear this bit to 0. If the software checks that this bit is 0, it means that this operation is completed.
2. The write operation to this register can only be performed when the module is not in the operation state (that is, when AES_CR.Start = 0), otherwise the hardware will automatically ignore the write operation. Read operations are not subject to this restriction.

22.2.2 Data register (AES_Data)

Offset address: 0x10~0x1C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Data[31:16]															
RW															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Data[15:0]															
RW															

Bit	Symbol	Description
31:0	Data	Store 128-bit plaintext / ciphertext of AES algorithm

Note:

1. The data register consists of four 32-bit registers consisting of 128-bit data, which are used to store the plaintext to be encrypted or the ciphertext to be decrypted before the module operation, and store the encrypted ciphertext or decrypted plaintext after the operation is completed.

Encryption operation		Decryption operation	
Before operation	After operation	Before operation	After operation
128-bit plaintext	128-bit ciphertext	128-bit ciphertext	128-bit plaintext

Four 32-bit registers are connected together to form a 128-bit data, and the four registers need to be operated separately during read and write operations. The operation sequence corresponding to the data register is as follows:

Data example: 0xFFEEDDCCBAA99887766554433221100

Offset address	Register name	Fill in data
0x10	AES_Data0	0x33221100
0x14	AES_Data1	0x77665544
0x18	AES_Data2	0xBBAA9988
0x1C	AES_Data3	0xFFEEDDCC

2. Writing to this register can only be done when the module is not in operation state (that is, when AES_CR.Start = 0), otherwise the hardware will automatically ignore the writing operation to this register.
3. The reading of this register can only be carried out when the module is not in the operation state (that is, when AES_CR.Start = 0), otherwise the reading of this register will get all 0s.

22.2.3 Key register (AES_Key)

Offset address: 0x20~0x3C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Key[31:16]															
RW															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Key[15:0]															
RW															

Bit	Symbol	Description
31:0	Key	Store 128, 192, 256 -bit keys of AES algorithm

1. The key register consists of eight 32-bit registers, which store the input initial key. The write operation needs to operate on 8 32-bit registers respectively. The corresponding sequence of operations is as follows:

128-bit key example: 0x0F0E0D0C_0B0A0908_07060504_03020100

Offset address	Register name	Fill in data
0x20	AES_Key0	0x03020100
0x24	AES_Key1	0x07060504
0x28	AES_Key2	0x0B0A0908
0x2C	AES_Key3	0x0F0E0D0C

192-bit key example: 0x17161514_13121110_0F0E0D0C_0B0A0908_07060504_03020100

Offset address	Register name	Fill in data
0x20	AES_Key0	0x03020100
0x24	AES_Key1	0x07060504
0x28	AES_Key2	0x0B0A0908
0x2C	AES_Key3	0x0F0E0D0C
0x30	AES_Key4	0x13121110
0x34	AES_Key5	0x17161514

256-bit key example: 0x1F1E1D1C_1B1A1918_17161514_13121110_0F0E0D0C_0B0A0908_07060504_03020100

Offset address	Register name	Fill in data
0x20	AES_Key0	0x03020100
0x24	AES_Key1	0x07060504
0x28	AES_Key2	0x0B0A0908
0x2C	AES_Key3	0x0F0E0D0C
0x30	AES_Key4	0x13121110
0x34	AES_Key5	0x17161514
0x38	AES_Key6	0x1B1A1918
0x3C	AES_Key7	0x1F1E1D1C

2. Writing to this register can only be done when the module is not in operation state (that is, when AES_CR.Start = 0), otherwise the hardware will automatically ignore the writing operation to this register.
3. The reading of this register can only be carried out when the module is not in the operation state (that is, when AES_CR.Start = 0), otherwise the reading of this register will get all 0s.

22.3 Exception mechanism

- Only 32-bit access is supported, and access to other bit widths will cause system exceptions and enter hardware exception interrupts.
- Accessing the offset address of the AES module greater than or equal to the address of 0x80 will cause a system exception and enter a hardware exception interrupt.

22.4 Operating instructions for this module

This module has two functions: encryption and decryption. The operations of the two functions have some common features. The following will first introduce the common points, and then introduce the standard operating procedures of each function.

22.4.1 IP operations

1. In the process of AES encryption and decryption, the data register will change. If the operated data of the next operation is the result of this operation, then there is no need to rewrite the data.
2. Support 128, 192 and 256-bit keys, 128-bit key write offset address 0x20~0x2C, 192-bit key write offset address 0x20~0x34, 256-bit key write offset address 0x20~0x3C.
3. The method of judging the end of the operation of the module: read AES_CR.Start continuously, if its value becomes 0, it means the end of the operation.

22.4.2 Encryption operation process

- Step 1: 128-bit data to be encrypted into the data register (AES_DATA).
- Step 2: Write the encryption key into the key register (AES_KEY).
- Step 3: Set AES_CR.KeySize according to key length
- Step 4: Set AES_CR.Mode to 0 to enable encryption mode.
- Step 5: Write 1 to AES_CR.Start in the control register to start the module to operate.
Step 3, Step 4 and Step 5 can be performed simultaneously.
- Step 6: Wait for the value of AES_CR.Start to return to 0, and the module operation ends.
- Step 7: Read the data register (AES_DATA) to obtain 128-bit ciphertext.

22.4.3 Decryption operation process

- Step 1: 128-bit data to be decrypted into the data register (AES_DATA).
- Step 2: Write the decryption key into the key register (AES_KEY).
- Step 3: Set AES_CR.KeySize according to key length
- Step 4: Set AES_CR.Mode to 1 to enable decryption mode.

Step 5: Write 1 to AES_CR.Start in the control register to start the module to operate.

Step 3, Step 4 and Step 5 can be performed simultaneously.

Step 6: Wait for the value of AES_CR.Start to return to 0, and the module operation ends.

Step 7: Read the data register (AES_DATA) to get 128 -bit plaintext.

22.4.4 Data example

128 -bit plaintext: 0xFFEEDDCCBAA99887766554433221100

128 -bit key: 0x0F0E0D0C0B0A09080706050403020100

22.5 Runtime instructions

The time required by this module from starting an operation (AES_CR.Start writes 1) to the end of the operation (AES_CR.Start returns to 0) is shown in Table 22-5:

Table 22-5 AES encryption and decryption running time

	128 -bit key	192 -bit key	256 -bit key
Encryption	220 cycles	260 cycles	300 cycles
Decrypt	290 cycles	332 cycles	398 cycles

23 Crystal-less USB Clock Calibrator (CTS)

The clock calibrator can adjust and calibrate the clock frequency of RCH48M, and can also adjust and calibrate the clock frequency of other RC oscillators, and can also be used as a general timer. The main function of this module is RCH48M automatic calibration, and other functions are additional functions when 48M automatic calibration is not used.

Adjustment and Calibration The RCH48M measures the frequency of the oscillator to be calibrated through an optional reference signal. The frequency of the oscillator can be automatically adjusted according to the measured frequency error, or manual adjustment can be used.

The RCH48M provides a precise clock for the USB peripherals, in this case, the base reference signal can be provided by the Start of Frame (SOF) packet signal on the USB bus, which is sent by the USB master at 1ms intervals. The USB module will generate a flip signal with a period of 2ms. The CTS system clock reference signal can also be provided by the XTL oscillator output or external pins, or generated by user software.

RCH24M oscillation calibration does not support automatic calibration, only manual adjustment is supported. The reference clock source can be flexibly selected.

The timer is a reload mode count timer that can generate a capture interrupt. Support low power wake-up.

23.148M clock calibration

23.1.1 System characteristics

Selectable Base Reference Source with Programmable Prescaler and Polarity

- USB SOF packet reception
- XTL oscillator output
- External pin

Base reference pulse can be generated by software

Oscillator automatic fine-tuning function without CPU participation

Manual software control option for faster calibration initiation

16 -bit frequency error counter for automatic error capture and reload

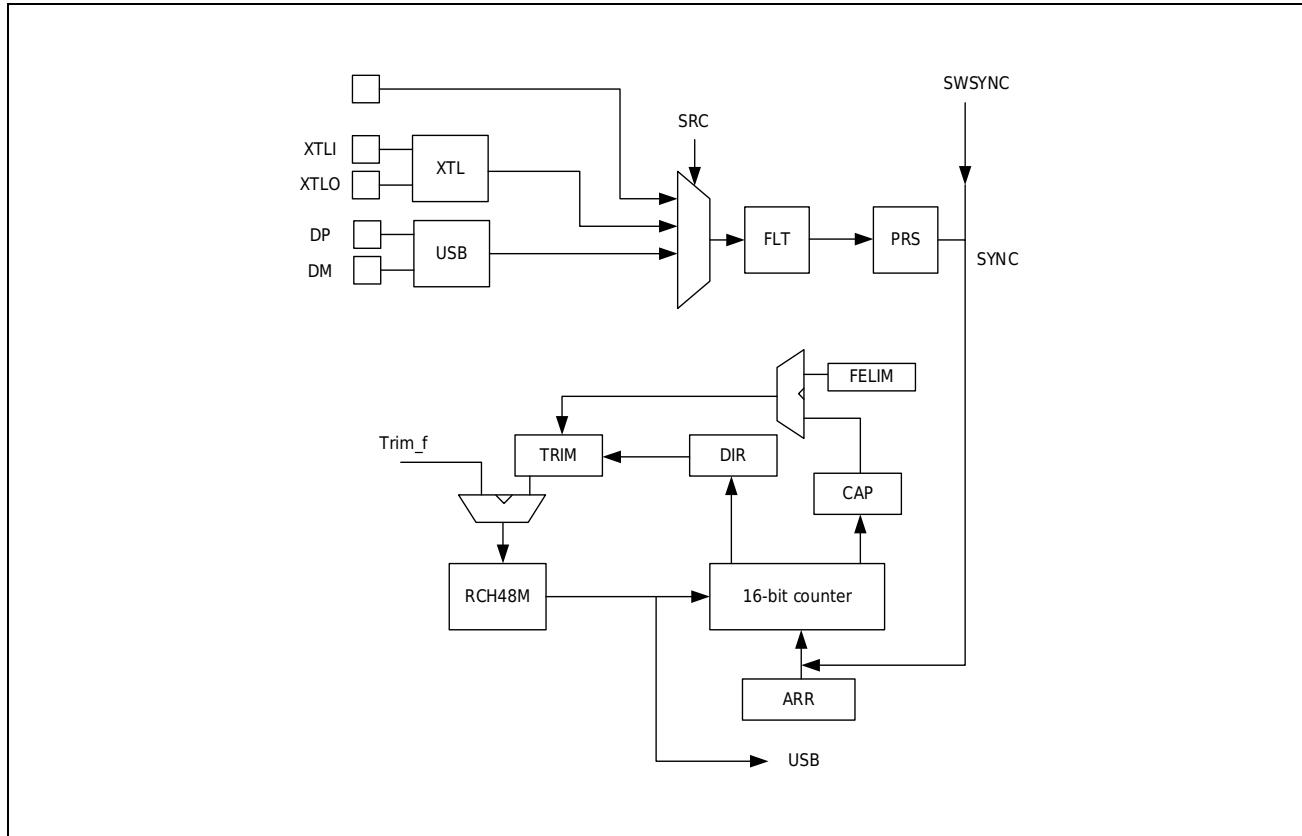

Programmable error limits for automatic frequency error values and status flags

Maskable interrupt

- Counter count underflow (UDF)
- Clock calibration is OK (OK)
- Clock Alignment Warning (WARN)

- Clock Calibration Error (ERR)

23.1.2 Block diagram

23.1.3 Reference source synchronization input

The clock calibration system reference source can be selected through the register CTS_CFGR, which can be an external pin signal, XTL clock, USB_SOF signal. To stabilize the reference signal input, it is configurable to use a simple digital filter to remove any interference. The signal source can also configure the polarity, and can be divided by a prescaler to obtain a synchronization signal within a reasonable frequency range (usually around 1mS).

The synchronization signal can also be generated by software by setting the SW_SYNC bit in the CTS_CR register to 1. When using SW_SYNC, select the reference clock as the pin signal, and ensure that the pin input level is low.

23.1.4 Frequency Error Measurement

The frequency error counter is a 16-bit down / up counter that reloads the ARR value on each SYNC event of the reference source. It starts counting down until it reaches a zero value, at which point a UDF (expected underflow) event is generated. It will then increment the count up to the OUTRANGE limit, in which case it will eventually stop counting (if no SYNC event is received) and generate a MISS event. The OUTRANGE limit is defined as the frequency error limit (FELIM field of the CTS_CFGR register) multiplied by 128.

SYNC event is detected, the actual value of the frequency error counter and its direction are stored in the FECAP (frequency error capture) field and FEDIR (frequency error direction) bit of the CTS_ISR register. When a SYNC event is detected during the down counting phase (before reaching the zero value), it means that the actual frequency is less than the target frequency (thus, the TRIM value should be incremented); when a SYNC event is detected during the up counting, it means that the actual frequency is greater than the target frequency (thus, the TRIM value should be decremented).

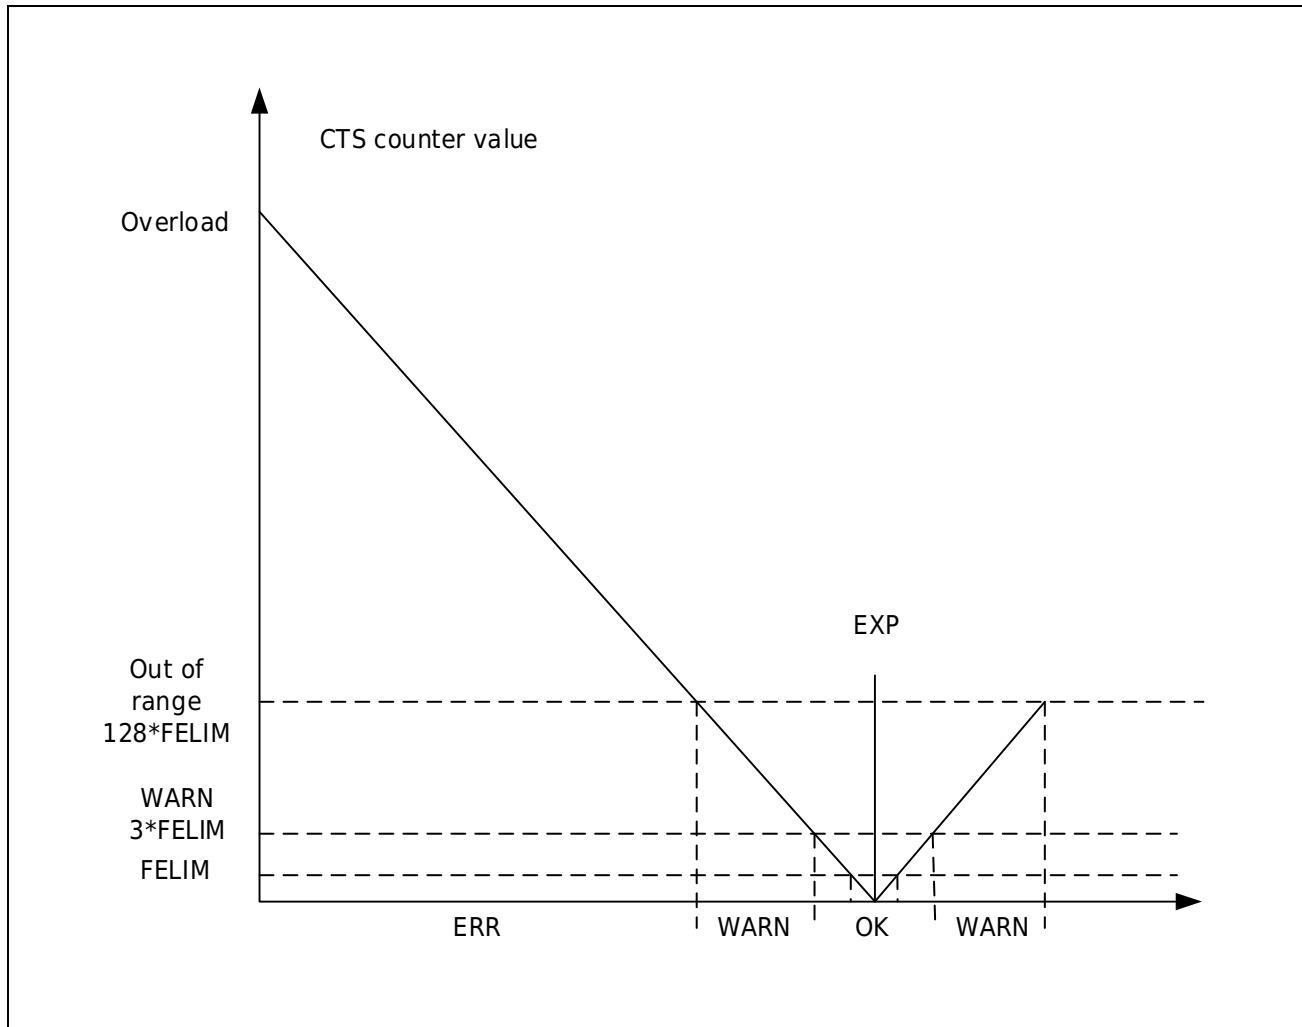

Figure 23-1 CTS Counter

23.1.5 Frequency error trimming

The measured frequency error is estimated by comparing the frequency value to a set of limits:

- TOLERANCE LIMIT (tolerance limit), given directly in the FELIM field of the CTS_CFG register
- WARNING LIMIT (warning limit), defined as $3 * \text{FELIM}$ value
- OUTRANGE (error limit), defined as $128 * \text{FELIM}$ value

The result of this comparison is used to generate a status indication and to control automatic trimming, which is enabled by setting the AUTO_TRIMEN bit in the CTS_CR register.

- When the frequency error is lower than the tolerance limit, it means that the actual trimming value in the TRIM field is the optimal value, so no trimming operation is required.
 - Indicate OK status
 - TRIM value in AUTOTRIM mode
- When the frequency error is below the warning limit but above or equal to the tolerance limit, it means some kind of trimming is required, but only one trimming step is needed to reach the optimal TRIM value.
 - Indicate OK status
 - Adjust TRIM value by ± 1 fine adjustment in AUTOTRIM mode
- When the frequency error is above or equal to the warning limit but below the error limit, it means that a stronger trim operation is required and there is a risk that the optimal TRIM value will not be reached in the next cycle.
 - Indicates WARN status
 - Adjust TRIM value by ± 2 fine adjustment in AUTOTRIM mode
- When the frequency error is higher than or equal to the error limit, it means that the frequency is out of the fine-tuning range. When the SYNC input is dirty or one of the SYNC pulses is missing (for example, when a USB SOF is corrupted). This also happens.
 - Indicates ERR or MISS status
 - TRIM value in AUTOTRIM mode

Note:

- If the actual value of the TRIM field is very close to its limit value, if it needs to be adjusted towards its limit value, it will only be adjusted to its limit value, and then the TRIM value remains at the limit value, and the OVF status will be indicated at this time.
- In AUTOTRIM mode (AUTO_TRIMEN bit set in CTS_CR register), the TRIM field of CTS_CR is trimmed by hardware and is read-only.

23.1.6 CTS initialization and configuration

ARR value

The ARR value should be chosen based on the ratio of the target frequency to the prescaled reference sync source frequency. This value is then decremented by 1 to achieve the desired synchronization at a value of zero. The specific formula is as follows:

$$\text{ARR} = (\text{fTARGET} / \text{fSYNC}) - 1$$

ARR field corresponds to a target frequency of 48 MHz and a sync signal frequency (SOF signal from USB) of 1 kHz.

FELIM value

FELIM value is closely related to the characteristics of the RCH48M oscillator and its typical fine-tuning step size. The optimal value corresponds to half the fine-tuning step size, expressed in ticks of the RCH48M oscillator clock. The following formulas can be used:

$$\text{FELIM} = (\text{fTARGET} / \text{fSYNC}) * \text{STEP[%]} / 100\% / 2$$

Results should always be rounded to the nearest integer value for best nudge response. If the application does not require frequent trimming operations, the trimming hysteresis can be increased by slightly increasing the FELIM value.

FELIM field corresponds to $(\text{fTARGET} / \text{fSYNC}) = 48000$ and a typical fine-tuning step size of 0.14%.

Note:

- Misconfiguring the ARR and FELIM fields fails to implement hardware protection, resulting in erratic fine-tuned responses. The intended mode of operation requires a correct setting of the ARR value (according to the sync source frequency), which is also greater than 128 * FELIM value (OUTRANGE limit).

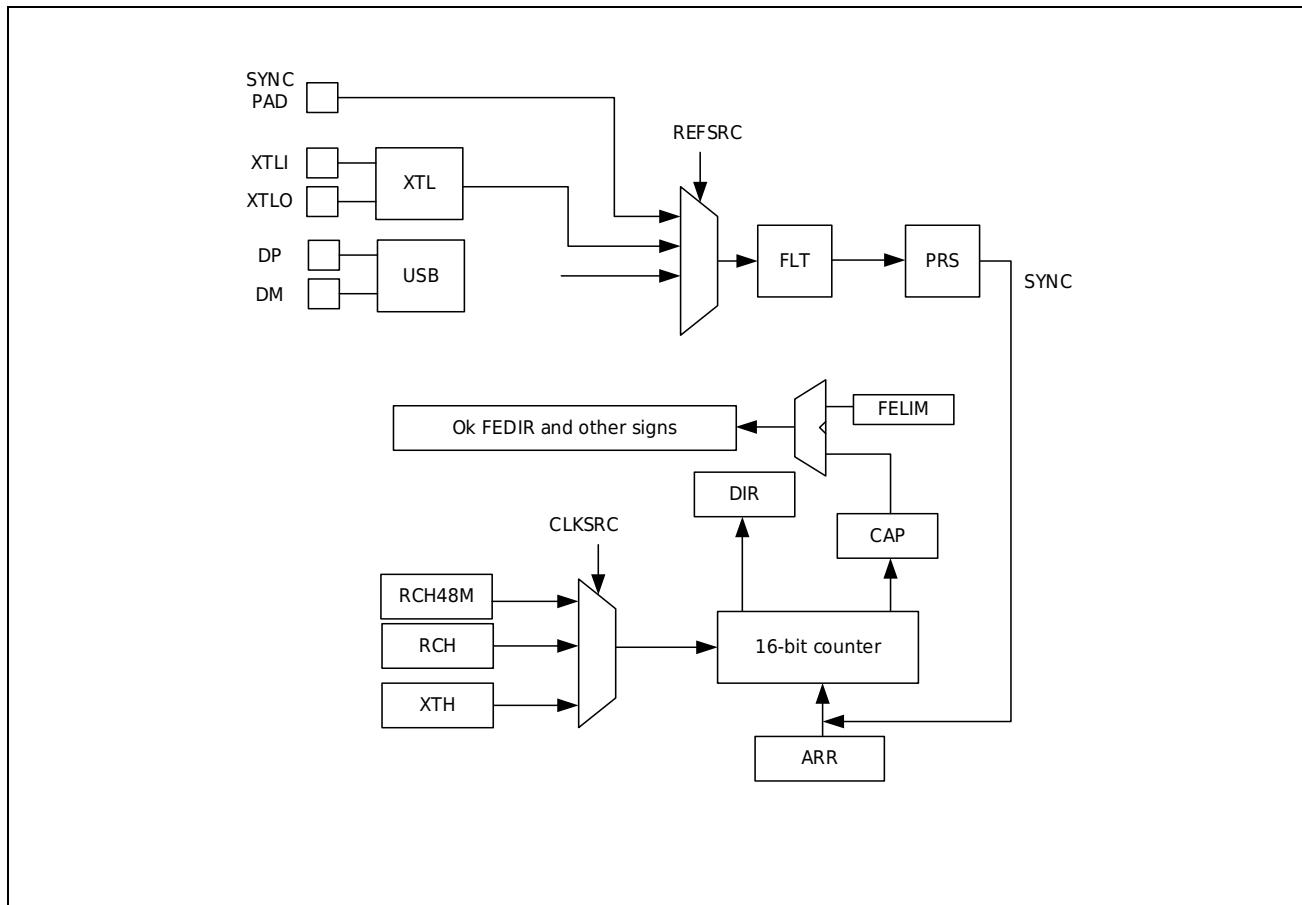

23.2 Other Oscillation Calibration

23.2.1 System characteristics

To calibrate the high-speed clock RCH reference clock, you can choose the port input.

When calibrating the low-speed clock RCL, use RCL as the reference clock, and select the counting clock as an accurate internal clock or an external input accurate clock.

23.2.2 Block diagram

23.2.3 Calibration Instructions

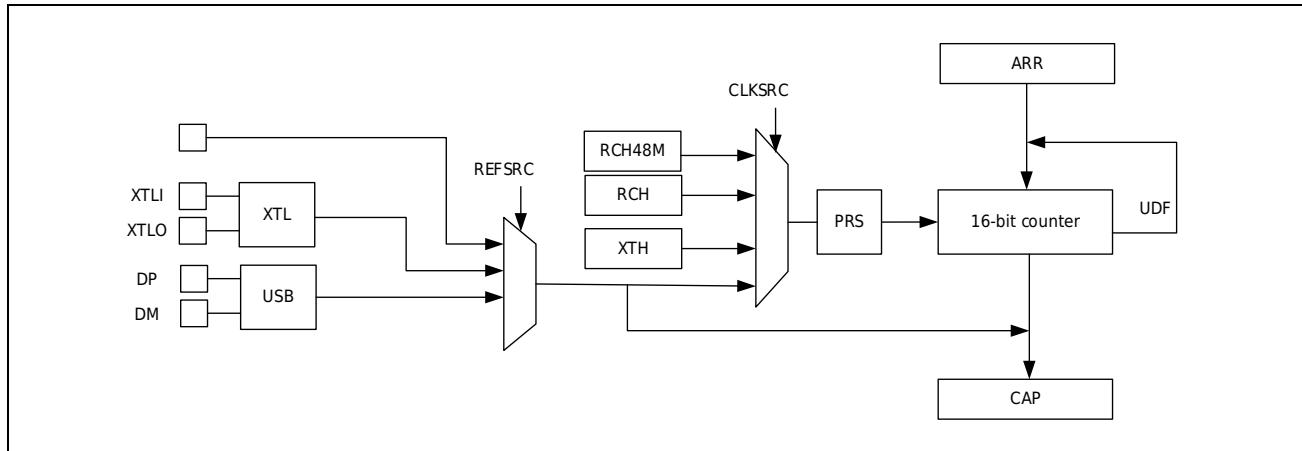

RCH Oscillation Calibration:

1. Set the reference clock as port input or precise XTL, and set the appropriate reference clock frequency division
2. Set the calibration clock to RCH
3. Set CFGR to set the target frequency and error range to be calibrated
4. Judge FEDIR in the interrupt service routine, if it is 1, increase the frequency value, increase the TRIM value; otherwise decrease

The TRIM value is initially set to the median value, and the value to be changed next time is 1/2 of the value to be changed last time, that is, the 2-point method. The 9-bit TRIM value can be calibrated 8 times.

23.3 Timer function description

23.3.1 Block diagram

Timer Features

- 16-bit down-counting auto-reload low-power timer
- Various clock sources can be configured
- 1/2/4/8/16/32/64/256 prescaler configurable
- Input capture function
- Timer wake-up function
- Support overflow interrupt, capture interrupt

23.3.2 Timer Clock Selection

The timer can choose internal high-speed clocks such as RCH48M, RCH, XTH, etc., or can choose external port input, low-speed XTL as counting clocks. When the high-speed clock is selected, the external input can realize the edge capture function of the rising edge or the falling edge.

23.3.3 Timer

The count value of the timer is counted down from ARR. When the count reaches 0, an underflow will occur. If the interrupt is enabled, an underflow interrupt will be generated. The counting cycle is ARR+1.

TIM_EN can only be changed when CEN is 0. When TIM_EN is 1 and CEN is written 1, the timer will reload the reload value to the timer.

23.4 CTS register

Base address 0x40005000

Table 23-1 CTS register

Register	Offset address	Description
CTS_CR	0x000	control register

24 Audio interface (I2S)

I2S features

- Support Philip / MSB / LSB / PCM mode
- Support MCK output
- Support 48K, 44.1K, 32K, 16K, 8K and other different audio sampling rates
- Support data length 16 bits, 24 bits, 32 bits
- Support frame length 16bit / 32bit
- Support DMA data transfer
- Support full-duplex transmission and reception (2 I2S cooperation)
- Support master sending and receiving
- Support slave sending and receiving
- Shared interrupt and port with SPI

24.1 Functional description

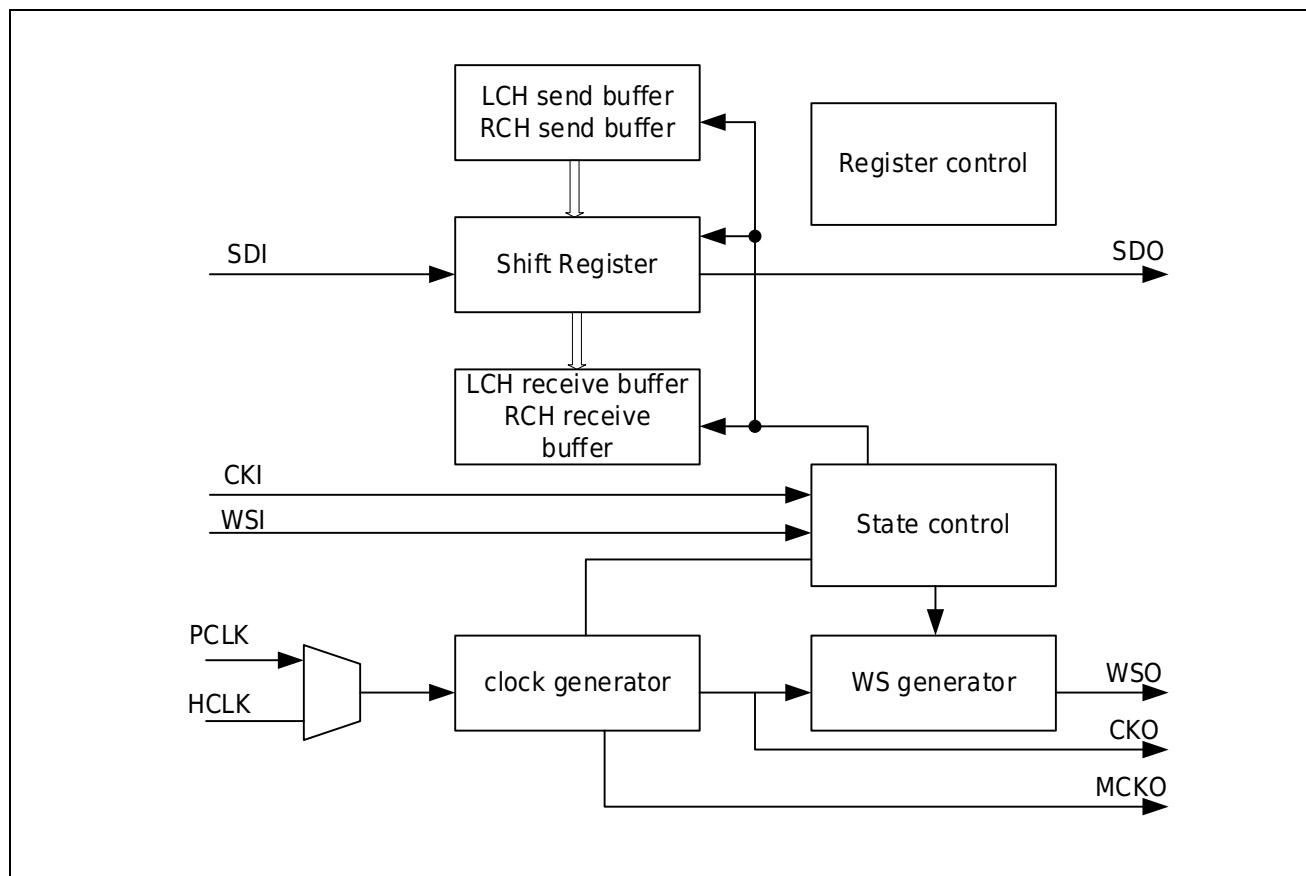

Figure 24-1 Functional block diagram

24.1.1 Pin multiplexing

I2S and SPI IO are multiplexed, and the multiplexing relationship is as follows:

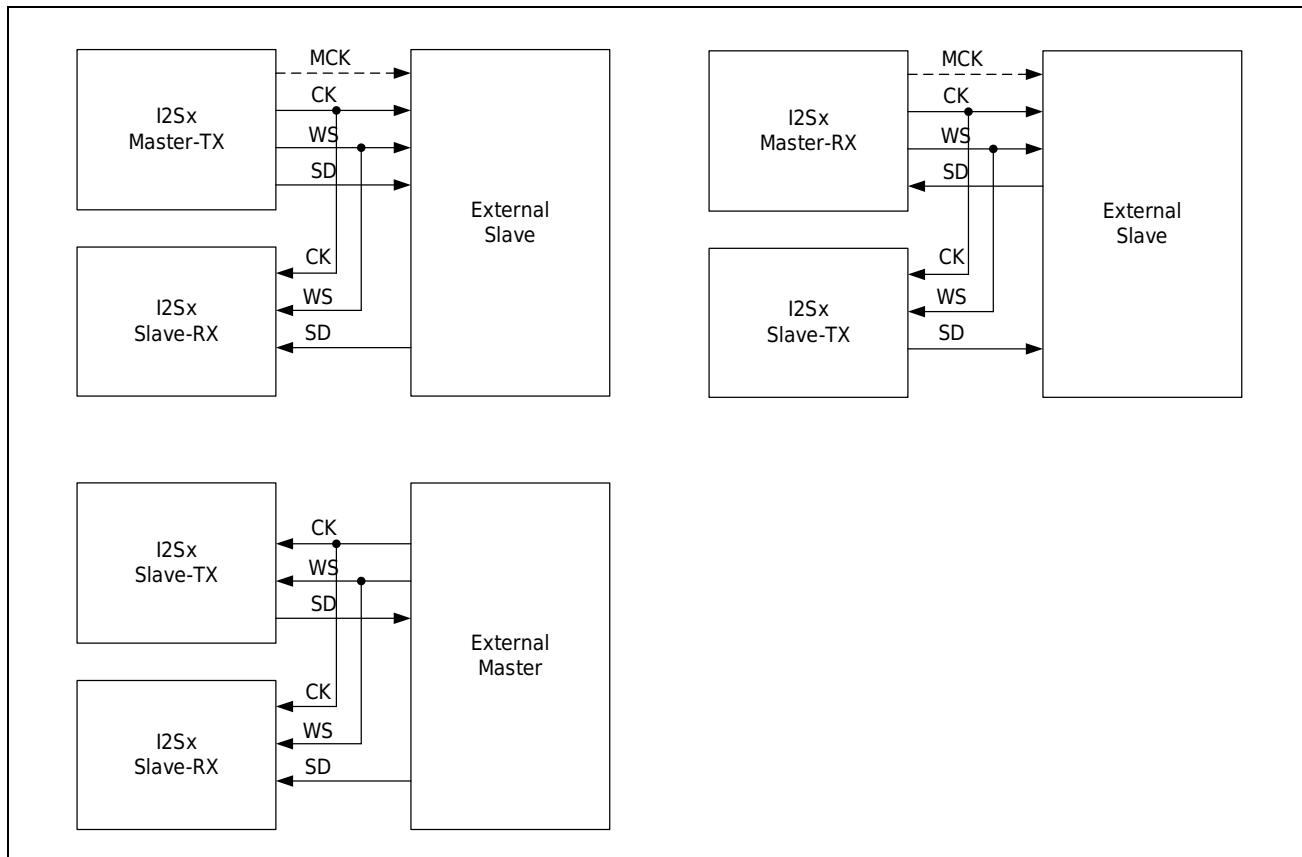

When the I2S function is enabled (the I2S bit in the SYSCtrl_Peripheral register is set to 1 and the SPI is invalid), the SPI and I2S multiplexed port is used as an audio I2S interface.

I2S	SPI	I2S pin description
SD	MOSI	Serial data (mapped to MOSI pin) for sending or receiving data on two time-division multiplexed data lanes (half-duplex mode only)
WS	NSS	Word Select (mapped to the NSS pin), is the data control signal output in master mode and the data control signal input in slave mode.
CK	SCK	Serial clock (mapped to the SCK pin), is the serial clock output in master mode and the serial clock input in slave mode.
MCK	MISO	Master Clock Output (MCK mapped to the MISO pin), when the I2S is configured in master mode (and the MCKOE bit in the I2Sx_PR register is set), this additional clock is output using the main clock (mapped separately), clocked at a preset rate of $256 \times f_s$ Configure frequency generation, where f_s is the audio signal sampling frequency.

I2S also has a set of independent IO settings, customers can use I2S and SPI at the same time. In this mode, the interrupt and SPI share the same interrupt entry address, and it is necessary to judge and process the corresponding interrupt service program according to the respective flags.

24.1.2 I2S full duplex

Each I2S supports master mode and slave mode, and supports half-duplex transmission and reception. If full-duplex mode is required, two I2S need to be used for cooperation.

24.2I2S audio protocol description

I2S needs to handle audio data which is usually time multiplexed on two channels left and right. However, there are two 16-bit registers for transmit or receive. Therefore, the software needs to write the value corresponding to the corresponding channel into the channel data register, and read the corresponding data from the corresponding channel data register. Always send the left channel data first, and then send the right channel data (for the PCM protocol, the right channel data is meaningless).

There are four combinations of data and frame formats, and data can be sent in the following formats:

- Pack 16-bit data in 16-bit frames
- Pack 16-bit data in 32-bit frames
- Pack 24-bit data in 32-bit frames
- Pack 32-bit data in 32-bit frames

When using 16-bit data in a 32-bit packet, only 16 bits of valid data need to be read and written, and 16 bits of invalid data are forced to zero without any software operations or DMA requests (just one read/write operation).

24-bit and 32-bit data frames require two CPU read or write operations to the I2Sx_DR register, or two DMA operations. For 24-bit data frames, the hardware will automatically fill in 8 0s to expand to 32 bits.

For all data formats and communication standards, the most significant bit is always sent first (MSB first).

The I2S interface supports four audio standards, which can be configured using the I2SSTD[1:0] and PCMSYNC bits in the I2Sx_CFGR register.

24.2.1 I2S Philips Standard

Use the WS signal to indicate which channel the data currently being sent belongs to. This signal is valid one clock before the first bit (MSB) of the current channel's data.

The sender changes the data on the falling edge of the clock signal (CK), and the receiver reads the data on the rising edge. WS signal also changes on the falling edge of CK.

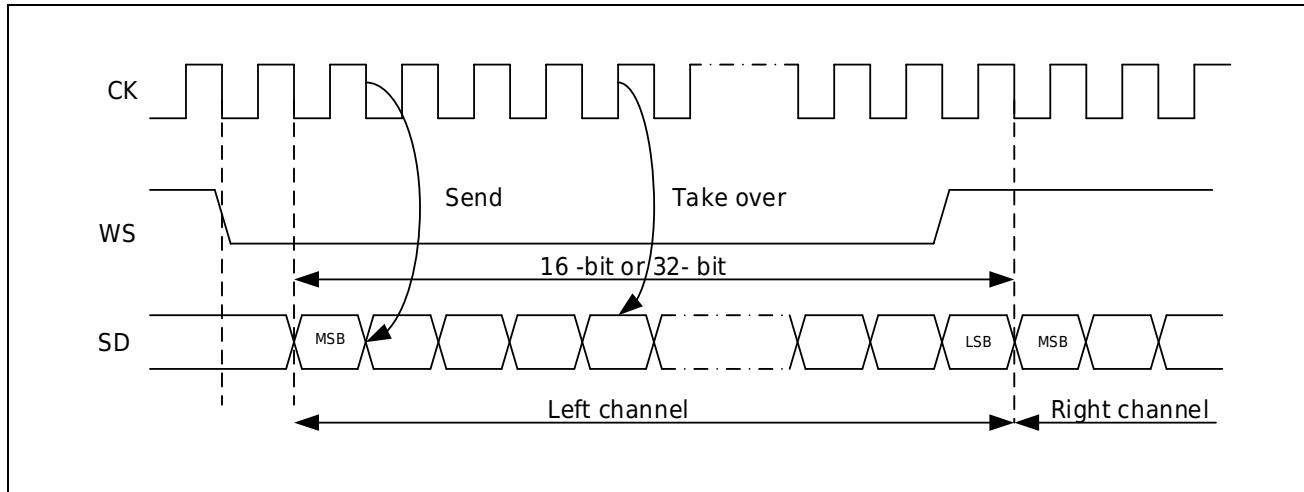

Figure 24-2 Philip Protocol WaveForm (16/32 bit full precision)

This mode requires two writes or reads to the I2Sx_DRL/I2Sx_DRR registers.

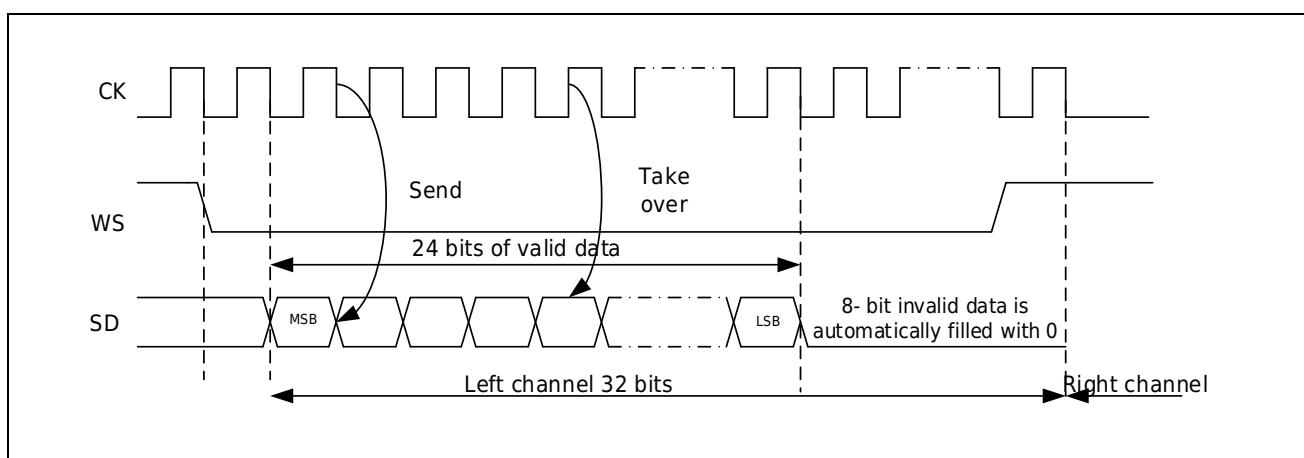

Figure 24-3 Philip Protocol Waveform (24-bit frame)

This mode requires two writes or reads to the I2Sx_DRL/I2Sx_DRD registers.

In sending mode, if you need to send 0x89ABCD, 0x8FEDCA (24 bits):

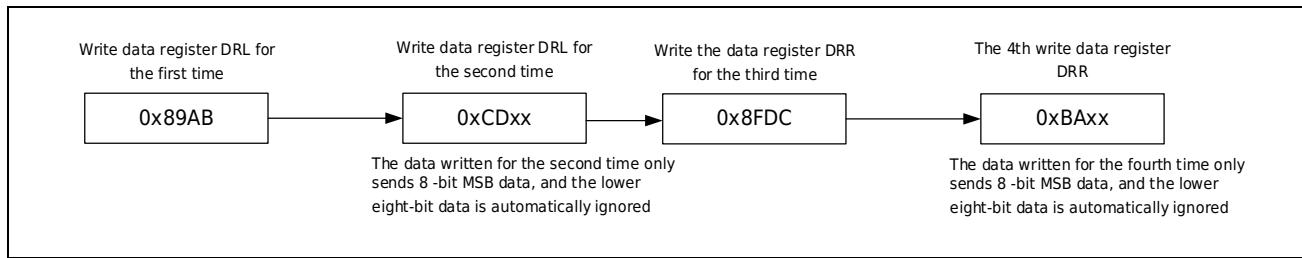

Figure 24-4 24 -Bit Data Transmission Write Operation

In receive mode, if receive data 0x123456,0x89ABCD:

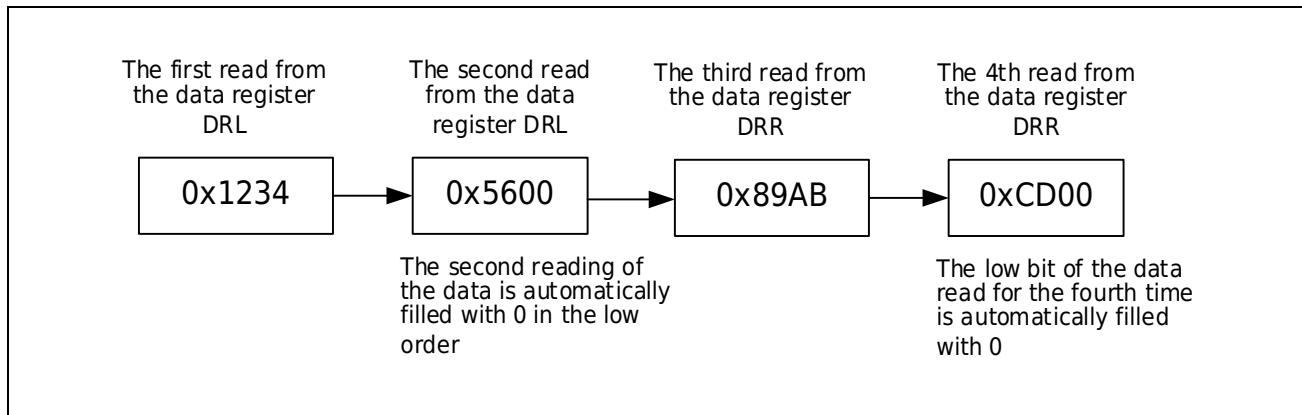

Figure 24-5 24 -Bit Data Mode Receive Read Operation

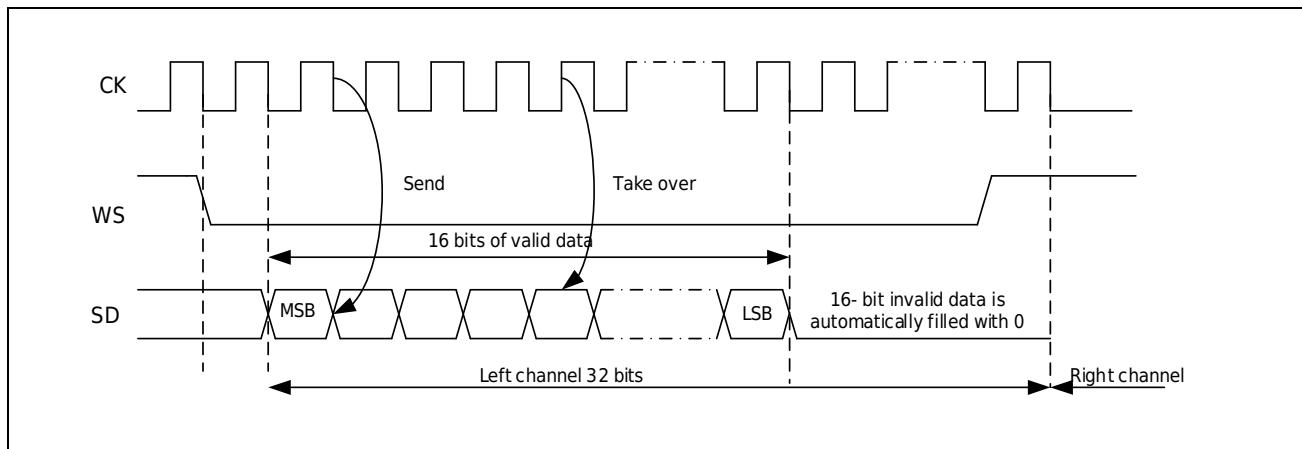

Figure 24-6 Philip Protocol 16 -Bit Extended To 32 -Bit Data Frame

If you choose to extend the 16-bit data frame to a 32-bit channel frame during the I2S configuration stage, you only need to access the I2Sx_DR register once. The other 16 bits will be automatically filled with 0 by hardware, without software participation.

If the data to be sent or received is 0xCDEF (0xCDEF0000 is extended to 32 bits), you need to perform the operations shown in the figure below.

Only one read and write of data
register DRL/DRR is required

0xCDEF

Figure 24-7 16 -Bit DataRead And Write Operations

When sending, each time the MSB is written into the data register I2Sx_DRL/R, after the data is transferred to the shift register, the TXE flag of the corresponding channel will be set to 1, and an interrupt will be triggered when the interrupt is enabled, and the new data to be sent Load into the I2Sx_DR register. This is true even though the lower 16 bits of 0x0000 filled by the hardware have not been sent, because the lower 16 bits are sent by the hardware.

When receiving, the first half word (high 16 bits) is received, the hardware will set the RXNE flag of the corresponding channel to 1, and trigger an interrupt if the interrupt is enabled.

24.2.2 MSB Alignment Standard

This standard generates the WS signal and the first data bit at the same time, the WS left channel corresponds to a high level, and the right channel corresponds to a high level.

The sender changes the data on the falling edge of the clock signal (CK), and the receiver reads the data on the rising edge. WS signal also changes on the falling edge of CK.

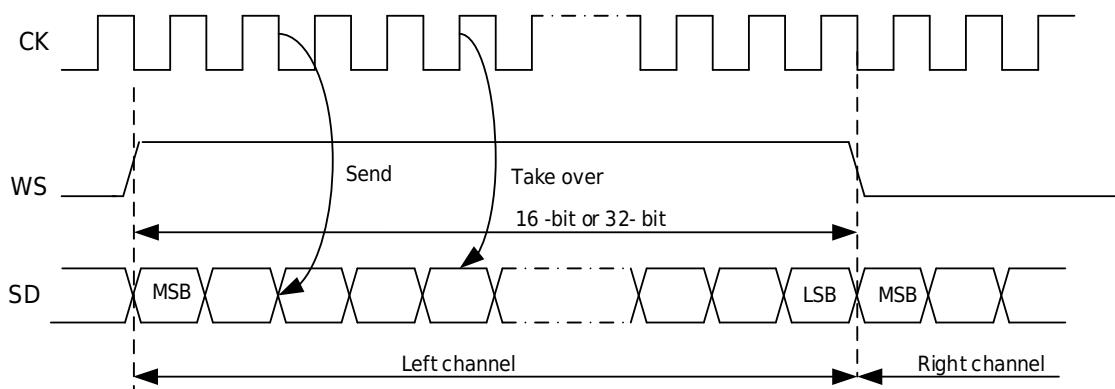

Figure 24-8 MSB protocol waveform (16/32 bit full precision)

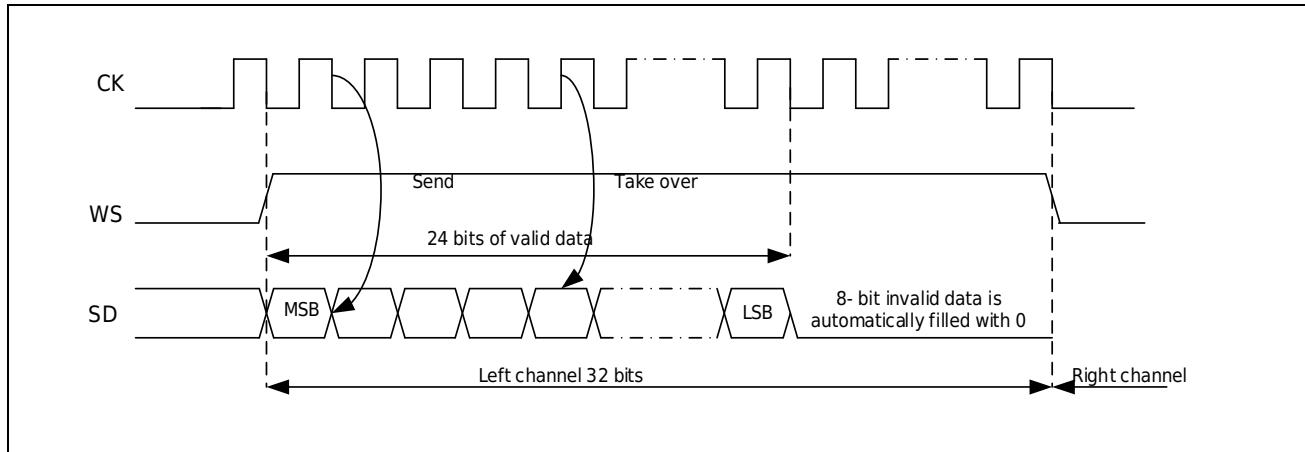

Figure 24-9 MSB protocol waveform (24-bit frame)

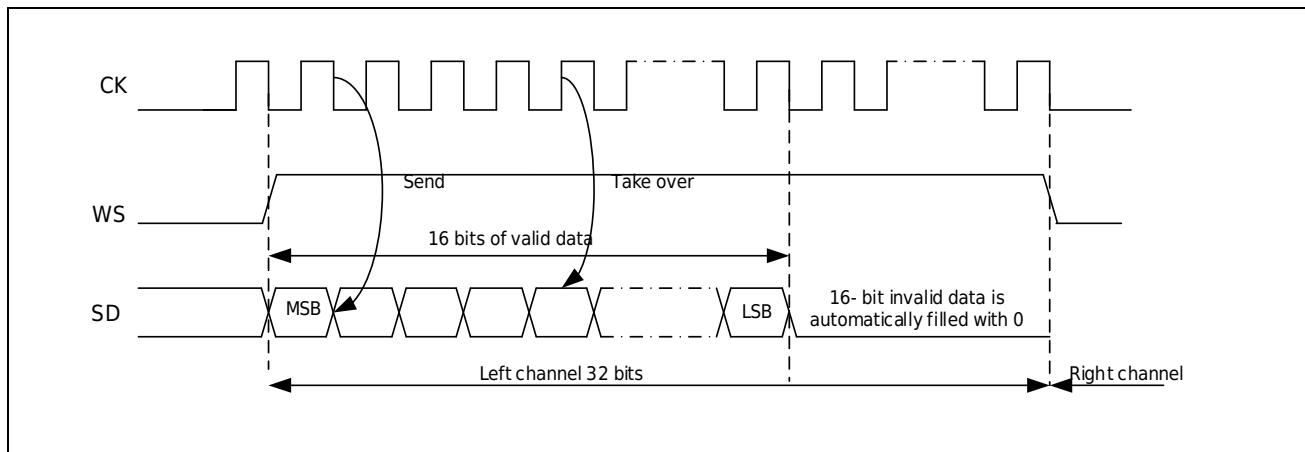

Figure 24-10 MSB Protocol 16 -Bit Extended To 32 -Bit Data Frame

24.2.3 LSB Alignment Standard

This standard is similar to the MSB alignment standard (for 16-bit and 32-bit full-precision frame formats, there is no difference).

The sender changes the data on the falling edge of the clock signal (CK), and the receiver reads the data on the rising edge. WS signal also changes on the falling edge of CK.

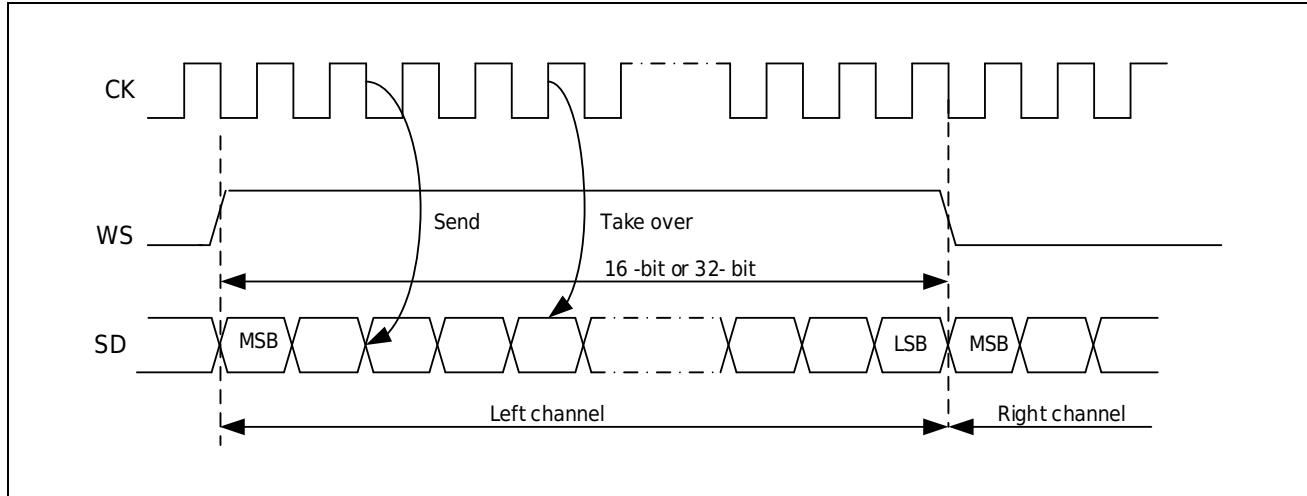

Figure 24-11 LSB protocol waveform (16/32 bit full precision)

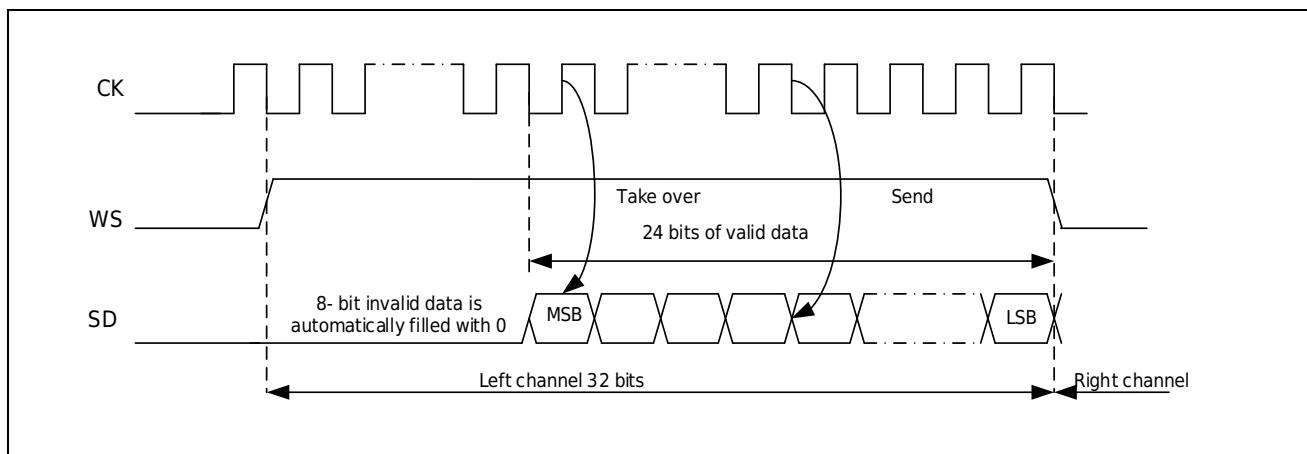

Figure 24-12 LSB protocol waveform (24-bit frame)

In transmit mode, if you need to send data 0x89ABCD, you need to perform two write operations to the I2Sx_DRL/I2Sx_DRR registers by software or DMA. These operations are given below.

Write data register DRL/DRR
for the first time Write data register DRL/DRR
for the second time

0xxx89

0xABCD

The data written for the first time only
sends 8-bit LSB data, and the high-order
eight-bit data is automatically ignored
and sent as 0

Figure 24-13 LSB 24 -Bit Data Transmission Write Operation

In receive mode, if data 0x123456 is received, two consecutive read operations to the I2Sx_DR register are required on each RXNE event.

First read from data register DRL/
DRR

0x0012

Second read from data register
DRL/DRR

0x3456

The high bit of the data read for the first
time is automatically filled with 0

Figure 24-14 LSB 24 -Bit Data Mode Receive Read Operation

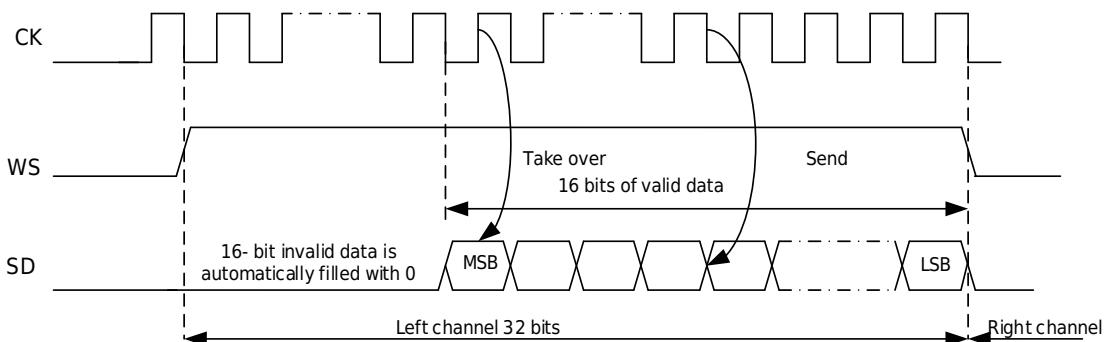

Figure 24-15 LSB Protocol 16 -Bit Extended To 32 -Bit Data Frame

If you choose to extend the 16-bit data frame to a 32-bit channel frame during the I2S configuration phase, you only need to access the I2Sx_DRL/I2Sx_DR register once. Extended to 32 bits, the upper half word (16 bits MSB) is set to 0x0000 by hardware.

If the data to be sent or received is 0x7893 (0x0000 7983 is extended 32-bit data), you need to perform the operations shown below.

Only one read and write of data register
DRL/DRR is required

0x7893

Figure 24-16 16 -Bit DataRead And Write Operations

In the send mode, when a TXE event occurs on the corresponding channel, the application program needs to write the data to be sent on the corresponding channel (in this example, it is 0x7893).

The 0x0000 field (extended to 32 bits) is sent first. After the valid data (0x7893) of the corresponding channel is transferred to the shift register, the TXE flag of the corresponding channel will be set to 1 again.

In receive mode, when a valid halfword is received (instead of the 0x0000 field), the RXNE of the corresponding channel is set.

24.2.4 PCM standard

For the PCM standard, there is no need to use channel information. Two PCM modes are available (Short Frame and Long Frame) and can be configured using the PCMSYNC bit in the I2Sx_CFGR register. PCM uses the rising edge to send data and the falling edge to receive data.

Sending data and receiving data only needs to use the I2Sx_DRL data register, and the I2Sx_DRR data register is invalid in this mode.

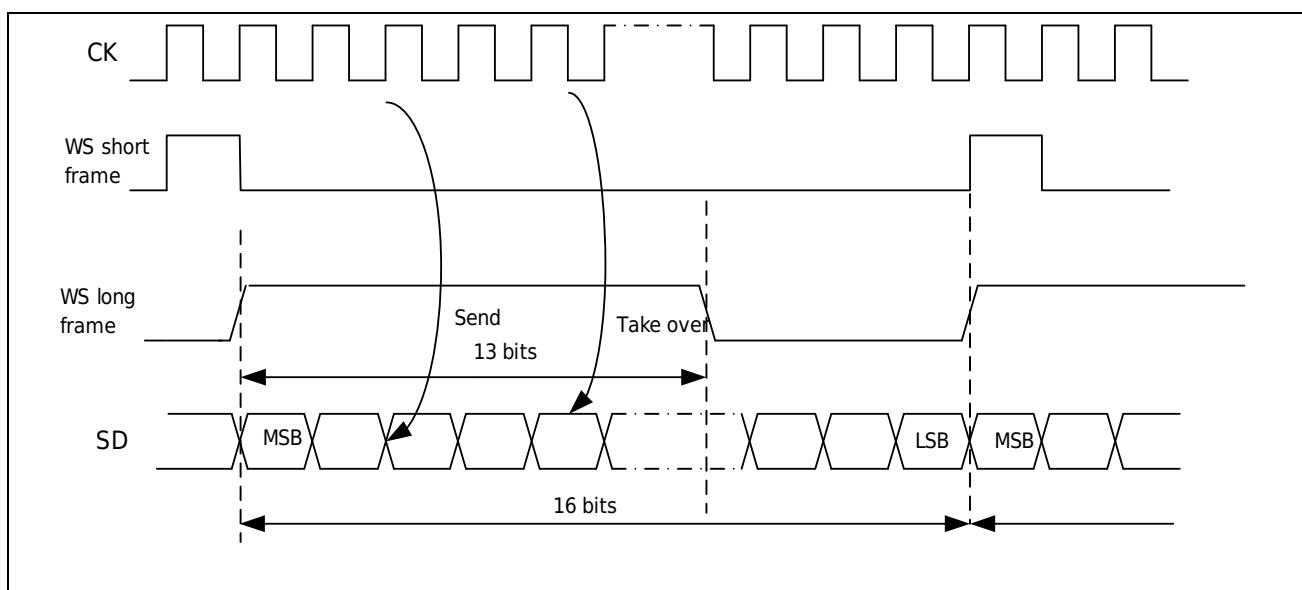

Figure 24-17 PCM protocol waveform (16 bits)

For long frame sync, the WS signal is maintained for 13 cycles in master mode.

For short frame sync, the duration of the WS sync signal is only one cycle.

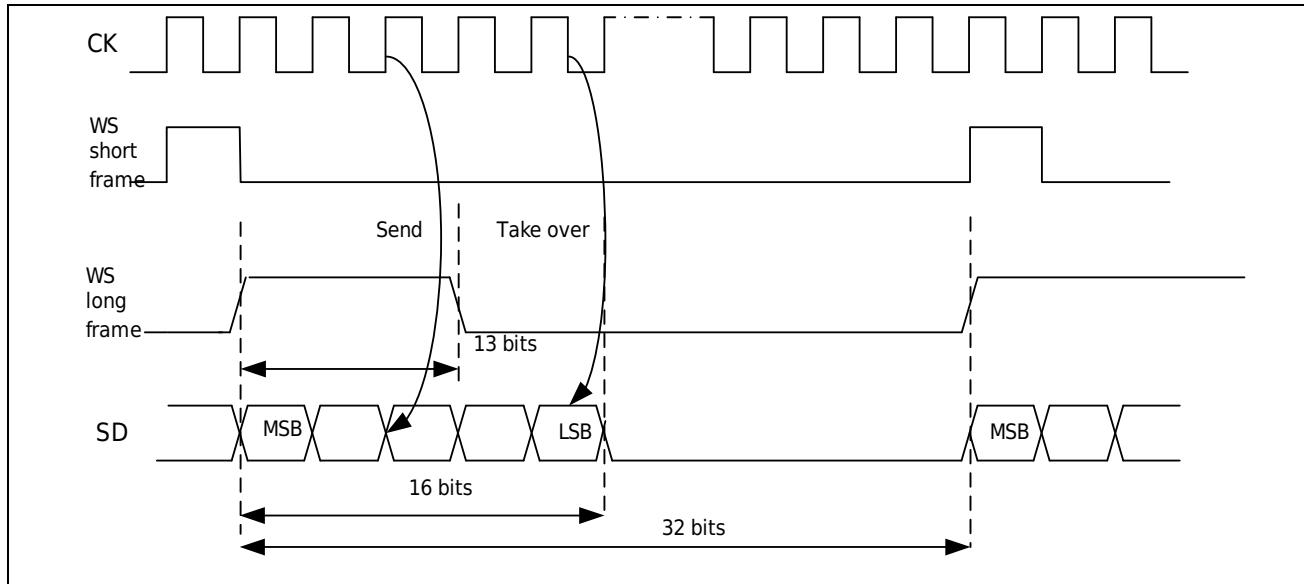

Figure 24-18 PCM Protocol Waveform (16-bit data extended to 32-bit)

Note:

- For two modes (host/slave mode) and two synchronizations (short/long synchronization), even in slave mode, you need to specify the number of bits between two sets of continuous data (and two synchronization signals) (I2Sx_CFGR register) DATLEN bit and CHLEN bit in).

24.3 I2S clock generator

The I2S bit rate is used to determine the data flow on the I2S data line and the I2S clock signal frequency.

I2S bit rate = number of bits per channel × number of channels × audio sampling frequency

For 16-bit dual-channel audio, the calculation formula for the I2S bit rate is as follows:

I2S bit rate = $16 \times 2 \times f_S$

If the packet is 32 bits wide, then I2S bitrate = $32 \times 2 \times f_S$.

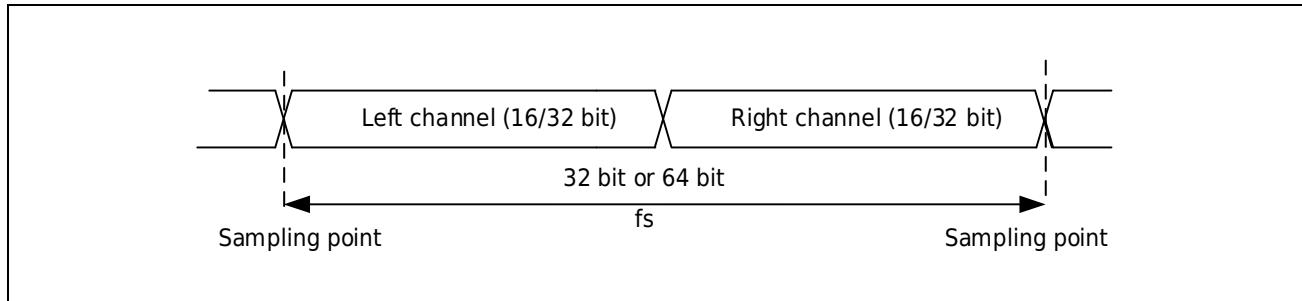

Figure 24-19 Audio Sampling Frequency Definition

When configuring master mode, the linear crossover needs to be set up correctly to communicate at the desired audio frequency.

The figure below shows the communication clock architecture. I2Sx clock can choose PCLK or HCLK.

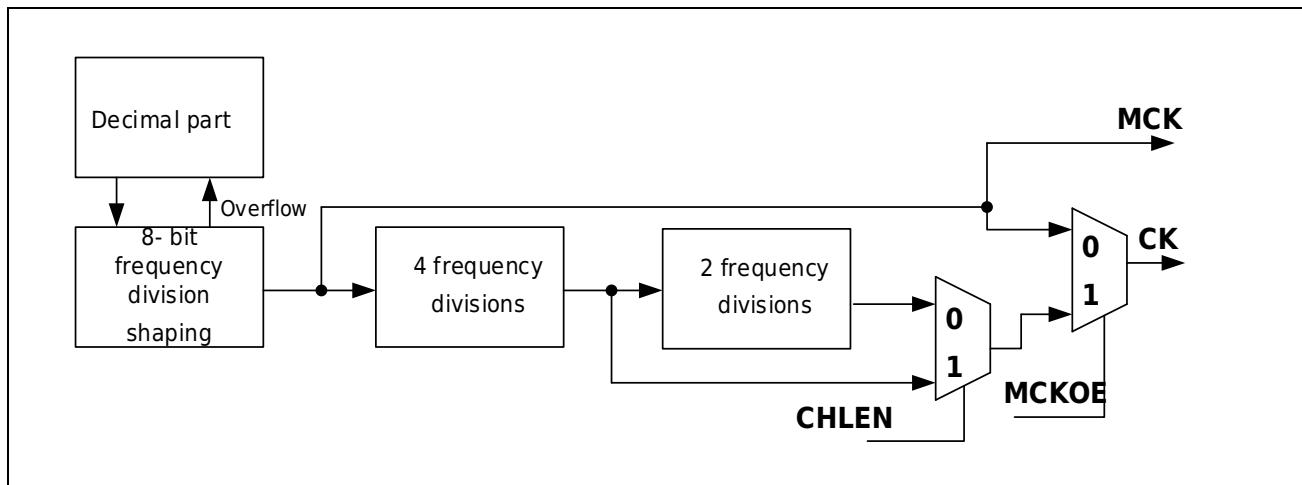

Figure 24-20 Clock Generation

The audio sampling frequency can be 96 kHz, 48 kHz, 44.1 kHz, 32 kHz, 22.05 kHz, 16 kHz, 11.025 kHz, or 8 kHz (or any other value within this range). To achieve the desired frequency, the linear divider needs to be programmed according to the following formula:

When the fractional frequency division FRACT is equal to 0x00:

When outputting the master clock (MCKOE in the I2Sx_PR register is set to 1):

$$f_S = I2SxCLK / [(16*2)*((2*I2SDIV)+ODD)*8] \text{ (when the channel frame width is 16 bits)}$$

$$f_S = I2SxCLK / [(32*2)*((2*I2SDIV)+ODD)*4] \text{ (when the channel frame width is 32 bits)}$$

master clock output is disabled (MCKOE bit is cleared):

$$f_S = I2SxCLK / [(16*2)*((2*I2SDIV)+ODD)] \text{ (when the channel frame width is 16 bits)}$$

$$f_S = I2SxCLK / [(32*2)*((2*I2SDIV)+ODD)] \text{ (when the channel frame width is 32 bits)}$$

the fractional frequency FRACT is not equal to 0x00:

When outputting the master clock (MCKOE in the I2Sx_PR register is set to 1):

$$f_S = I2SxCLK / \{ (16*2)* [2*(I2SDIV+FRACT/64)]*8 \} \text{ (when the channel frame width is 16 bits)}$$

$$f_S = I2SxCLK / \{ [(32*2)*[2*(I2SDIV+FRACT/64)]*4 \} \text{ (when the channel frame width is 32 bits)}$$

master clock output is disabled (MCKOE bit is cleared):

$$f_S = I2SxCLK / \{ (16*2)* [2*(I2SDIV+FRACT/64)] \} \text{ (when the channel frame width is 16 bits)}$$

$$f_S = I2SxCLK / \{ (32*2)* [2*(I2SDIV+FRACT/64)] \} \text{ (when the channel frame width is 32 bits)}$$

The following table provides the settings and accuracy values of the clock 48M clock for different sampling rates (without fractional frequency division).

I2S CLK	Channel Length	I2SDIV	I2SODD	MCLK	Sampling rate	Actual Frequency	Error%	freq(mck)
48000000	16	8	0	No output	96000	93750	-2.34	0

24.4 I2S working mode

24.4.1 I2S host mode

I2S can be configured as master mode. This means that the serial clock will be output on the CK pin and the word select signal will be generated on the WS pin. The main clock (MCK) can be output or not, which is controlled by the MCKOE bit in the I2Sx_PR register.

Step:

1. Set the I2SDIV[7:0] bits of the I2Sx_PR register to define the serial clock baud rate to achieve the corresponding audio sampling frequency. The ODD and FRACT bits of the I2Sx_PR register are set as required.
2. If the master clock MCK is required for the external DAC/ADC audio components, set the MCKOE bit of the I2Sx_PR register to 1 (I2SDIV and ODD (FRACT)) The value should be calculated based on the state of the MCK output. See Clock Generators for details.
3. Select the I2S standard through the I2SSTD[1:0] and PCMSYNC bits, select the data length through the DATLEN[1:0] bits and select the number of bits per channel by configuring the CHLEN bits. Additionally, the I2S master mode and direction (transmitter or receiver) are selected by the I2SCFG[1:0] bits of the I2Sx_CFGR register.
4. If desired, all possible interrupt sources and DMA functions are selected by writing to the I2Sx_CR2 register.
5. The I2SE bit of the I2Sx_CFGR register must be set to 1.

The IO of WS and CK is configured as output mode. If the MCKOE bit of I2Sx_PR is set, MCK also needs to be configured as an output.

Send sequence

The transmit sequence begins as soon as the halfword is written to the transmit buffer.

Assume that the first data of the left channel written to the sending buffer is written into the data register L; the first data of the right channel written into the sending buffer is written into the data register R. When data is transferred from the transmit buffer to the shift register, TXE of the corresponding channel is set to 1, and the data corresponding to the corresponding channel must be written to the transmit buffer of the corresponding channel.

A complete frame means that the left channel data is sent first and then the right channel data is sent. There are no partial frames where only the left channel is sent.

During first-bit transmission, data is loaded into the 16-bit shift register in parallel as a halfword, then shifted in serial and output on the MOSI/SD pin (MSB first). Every time data is transferred from the transmit buffer to the shift register, the TXE flag of the corresponding channel will be set to 1, and an interrupt will be generated if the TXEIE bit of the I2Sx_CR2 register is set to 1.

See the I2S Audio Protocol Description for more details on write operations in various I2S standard modes.

To ensure continuous audio data transmission, the next data to be transmitted must be written into the I2Sx_DRL/DRR register before the current data transmission ends.

To turn off I2S by clearing I2SE, one must wait for TXE = 1 and BSY = 0.

Receive sequence

This working mode is the same as the sending mode, only the 3rd point is different (please refer to the steps described in the I2S master mode), that is, the master device receiving mode is set by the I2SCFG[1:0] bits.

Audio data is always received in 16-bit packets regardless of data or channel length. This means that whenever the corresponding channel buffer has received data, the RXNE flag of the corresponding channel is set to 1, and if the RXNEIE bit of the I2Sx_CR2 register is set to 1, an interrupt will also be generated. Received audio values of the right or left channel can be entered into the corresponding channel's receive buffer with one or two receive operations, depending on the data and channel length configuration.

Reading the I2Sx_DRL/DRR register clears the RXNE bit of the corresponding channel.

See the I2S Audio Protocol Description for more details on read operations in various I2S standard modes.

If new data is received while previously received data has not been read, an overflow error will be generated and the OVR flag will be set. The value of the data reception register keeps the previous value, and the currently received data is lost.

If the ERRIE bit of the I2Sx_CR2 register is set, an interrupt will be generated to indicate the error.

To turn off I2S, specific actions need to be taken to ensure that I2S completes transfer cycles correctly without initiating new data transfers. The sequence depends on the configuration of data and channel lengths, and the selected audio protocol mode. In the following cases:

Extended 16 -bit data length on 32 -bit channel length (DATLEN = 00 and CHLEN = 1), using LSB-aligned mode (I2SSTD = 10)

- a) Wait for the penultimate RXNE = 1 ($n - 1$)
- b) Then wait 17 I2S clock cycles (using software loop)
- c) Disable I2S (I2SE = 0)

16 -bit data length extended on 32 -bit channel length (DATLEN = 00 and CHLEN = 1), using MSB aligned, I2S or PCM mode (I2SSTD = 00, I2SSTD = 01 or I2SSTD = 11, respectively)

- a) Waiting for the last RXNE
- b) Then wait 1 I2S clock cycles (using software loop)

- c) Disable I2S (I2SE = 0)

For all other combinations of DATLEN and CHLEN, regardless of the audio mode selected by the I2SSTD bits, the following sequence will be executed to turn off I2S:

- a) Wait for the penultimate RXNE = 1 ($n - 1$)
- b) Then wait for one I2S clock cycle (using a software loop)
- c) Disable I2S (I2SE = 0)

Note: During transmission, the BSY flag remains low.

24.4.2 I2S slave mode

For slave configuration, I2S can be configured in transmit mode or receive mode.

The rules followed by this working mode are basically the same as the I2S master mode configuration. In slave mode, the I2S interface does not generate a clock.

Clock and WS signals are input from an external master device connected to the I2S interface. This way, the user does not need to configure the clock.

The following configuration steps should be followed:

1. Select the I2S standard by the I2SSTD[1:0] bits, select the data length by the DATLEN[1:0] bits and select the number of bits for each channel in the frame by configuring the CHLEN bits. In addition, the mode of the slave device (transmit or receive) is selected by the I2SCFG[1:0] bits of the I2Sx_CFGR register.
2. If desired, all possible interrupt sources and DMA functions are selected by writing to the I2Sx_CR2 register.
3. The I2SE bit of the I2Sx_CFGR register must be set to 1.

Send sequence

The transmit sequence starts when the external master sends a clock and requests data transfer through the I2Sx_WS signal. The slave must be enabled before the external master can begin communication. The I2S data register must also be loaded before the master device can start communication.

For I2S, MSB alignment and LSB alignment modes, the first data to be sent is the left channel data, and the corresponding channel data is written in the left and right channel data registers respectively. When communication starts, data is transferred from the transmit buffer to the shift register. TXE flag of the corresponding channel is then set to 1 to request that the next data of the corresponding channel be written into the I2S corresponding channel data register.

The slave needs to be ready to send the first data before the master can generate the clock. Setting WS means that the left channel data is sent first.

Note: I2SE must be asserted at least 2 PCLK cycles before the first clock from the master appears on the CK line.

During first bit transmission, data is loaded in parallel from the internal bus as a halfword into the 16 -bit shift register, then shifted in serial and output to the MOSI/SD pin (MSB first). Every time data is transferred from the transmit buffer to the shift register, the TXE flag of the corresponding channel will be set to 1, and an interrupt will be generated if the TXEIE bit of the I2Sx_CR2 register is set to 1.

Note that writing to the transmit buffer can only be attempted when the TXE flag is 1.

I2S Audio Protocol Description for more details on write operations in the various I2S standard modes.

In order to ensure continuous audio data transmission, the next data to be sent must be written into the I2Sx_DRL/R register before the end of the current data transmission. If the first clock edge of the next data communication arrives before data has been written to the I2Sx_DR register, the underflow flag will be set and an interrupt may be generated. In this way, the software is informed that the transmitted data is incorrect. If the ERRIE bit of the I2Sx_CR2 register is set, an interrupt will be generated when the UDR flag in the I2Sx_SR register becomes 1. In this case, I2S must be turned off and the data transfer restarted from the left channel.

To turn off I2S by clearing the I2SE bit, one must wait for TXE = 1 and BSY = 0.

Receive sequence

This working mode is the same as the sending mode, only the first point is different (see the steps described in the I2S slave mode), that is, the slave device receiving mode is set through the I2SCFG[1:0] bits of the I2Sx_CFGR register.

Regardless of data length or channel length, audio data is always received in 16 -bit packets. This means that whenever the receive buffer has data, the RXNE flag of the corresponding channel in the I2Sx_SR register is set, and an interrupt will also be generated if the RXNEIE bit of the I2Sx_CR2 register is set. The received audio value of the right channel or left channel may enter the receive buffer of the corresponding channel through one or two receive operations, depending on the data length and channel length configuration.

Each time the received data is read from the data register of the corresponding channel, reading the I2Sx_DR register will clear the RXNE bit.

See the I2S Audio Protocol Description for more details on read operations for the various I2S standard modes.

If new data is received while previously received data has not been read, an overflow error will be generated and the OVR flag will be set. If the ERRIE bit of the I2Sx_CR2 register is set, an interrupt will be generated to indicate the error.

To turn off I2S in receive mode, I2SE must be cleared immediately after receiving the last RXNE = 1.

Note: The external master should be able to send / receive data in 16 -bit or 32 -bit packets over the audio channel.

24.5I2S Status Flags

The application program can fully monitor the status of the I2S bus through three status flags.

24.5.1 Busy flag (BSY)

BSY flag is set and cleared by hardware (writing to this flag has no effect). This flag indicates the status of the I2S communication layer.

BSY is set to 1, it means that I2S is busy communicating. In master receive mode (I2SCFG = 11), the exception is the BSY flag, which remains low during reception.

If software needs to disable I2S, the BSY flag can be used to detect the end of the transfer. This avoids corrupting the last transmitted data. To do this, the steps described below must be strictly followed.

At the beginning of the transfer (except when I2S is in master receiver mode), set the BSY flag to 1

The BSY flag is cleared by hardware when:

- When the transfer is complete (except for master send mode, where communication is continuous)
- When I2S is disabled

When communication continues:

- In master transmit mode, the BSY flag remains high during all transmissions
- In slave mode, the BSY flag goes low between each transfer for one I2S clock cycle

Note: Do not use the BSY flag to process each data transmission or reception, it is better to use the TXE flag and the RXNE flag instead.

24.5.2 Send buffer is empty (TXE_L TXE_R)

If this flag is set to 1, it means that the send buffer is empty and the data to be sent can be loaded into it. TXE flag is reset when the transmit buffer already contains data to be transmitted. This flag is also reset when I2S is disabled (I2SE bit reset).

24.5.3 Receive buffer is not empty (RXNE_L RXNE_R)

When this flag is set, it indicates that there is valid received data in the receive buffer. This flag is reset when the I2Sx_DRL/R register is read.

24.5.4 Underflow flag (UDR)

In transmit mode, this flag will be set if the first data transmit clock occurs before software has loaded any value into I2Sx_DR. An interrupt can be generated if the ERRIE bit in the I2Sx_CR2 register is set.

The UDR bit is cleared by I2Sx_ICLR.

24.5.5 Overflow flag (OVR)

This flag will be set if new data is received when the previous data has not been read from the I2Sx_DR register. Therefore, incoming data will be lost. An interrupt can be generated if the ERRIE bit in the I2Sx_CR2 register is set.

In this case, the contents of the receive buffer will not be updated with new data received. Execution of the I2Sx_DR register

A read operation will return data previously received correctly. All other halfwords subsequently transmitted by the master will be lost.

To clear the OVR bit, first perform a read operation on the I2Sx_DR register, followed by a read access to the I2Sx_SR register.

24.5.6 Framing Error Flag (FRE)

This flag can be set by hardware only when the I2S is configured in slave mode. This flag will be set if the external master does not change the WS line as the slave expects. If synchronization is lost, recover from this state and connect the external master with the

To resynchronize the I2S slave, perform the following steps:

1. Disable I2S.
2. It is re-enabled when the correct level is detected on the WS line (WS line is high in I2S mode, low in MSB- aligned, LSB- aligned, or PCM modes).

Synchronization failure between master and slave may be due to noise interference on SCK communication clock or WS frame sync signal line. An error interrupt can be generated if the ERRIE bit is set. The sync failure flag (FRE) is cleared by software operation I2Sx_ICLR.

24.6 I2S Interrupt DMA

The following table is the I2S interrupt list

Interrupt event	Event flag	enable control
Send buffer empty	TXE_L TXE_R	TXEIE
Receive buffer is not empty	RXNE RXNE_R	RXNEIE
Overflow error	OVR	ERRIE
Underflow error	UDR	
Frame error	FRE	

DMA features

In I2S mode, the data sent and received can be transferred using DMA.

25 USB2.0 Full Speed Module (USBFS)

25.1 Introduction to USBFS

The USB Full Speed (USBFS) controller provides a set of USB communication solutions for portable devices. The USBFS controller supports device mode, and the chip integrates a full-speed PHY. Support full speed (FS, 12Mb/s) transceiver in device mode. The USBFS controller supports all four transfer modes defined by the USB2.0 protocol (control transfer, bulk transfer, interrupt transfer, and isochronous transfer).

25.2 Main Features of USBFS

There are two main categories: general features and device mode features.

25.2.1 General features

- Built-in on-chip USB2.0 full-speed PHY
- Support device mode
- The module is embedded with DMA, and the AHB burst transfer type can be configured by software
- Power-saving features such as USB suspend, stop RAM clock, stop PHY domain clock
- 1.25KB of dedicated RAM with advanced FIFO control
- The RAM space can be divided into different FIFOs for flexible and effective use of RAM
- Each FIFO can store multiple packets
- Dynamically allocate memory
- The size of the FIFO can be configured as a non-power-of-two value, so that the storage unit can be used continuously
- No application intervention is required within one frame to achieve maximum USB bandwidth

25.2.2 Device Mode Properties

- The device mode supports USB 2.0 full speed (FS, 12Mb/s) transmission.
- 1 bidirectional control endpoint 0
- 4 IN endpoints (1, 3, 5, 7), can be configured as bulk transfer, interrupt transfer or isochronous transfer
- 4 OUT endpoints (2, 4, 6, 8), can be configured as bulk transfer, interrupt transfer or isochronous transfer
- 8 endpoints can be configured as synchronous transmission (periodic transmission) mode
- Contains an aperiodic transmit FIFO (shared by all aperiodic IN endpoints), a periodic transmit FIFO (exclusively shared by periodic IN endpoints) and a receive FIFO (shared by all OUT endpoints)
- Support remote wake-up function.

- Support soft disconnect function

25.3 USBFS System Block Diagram

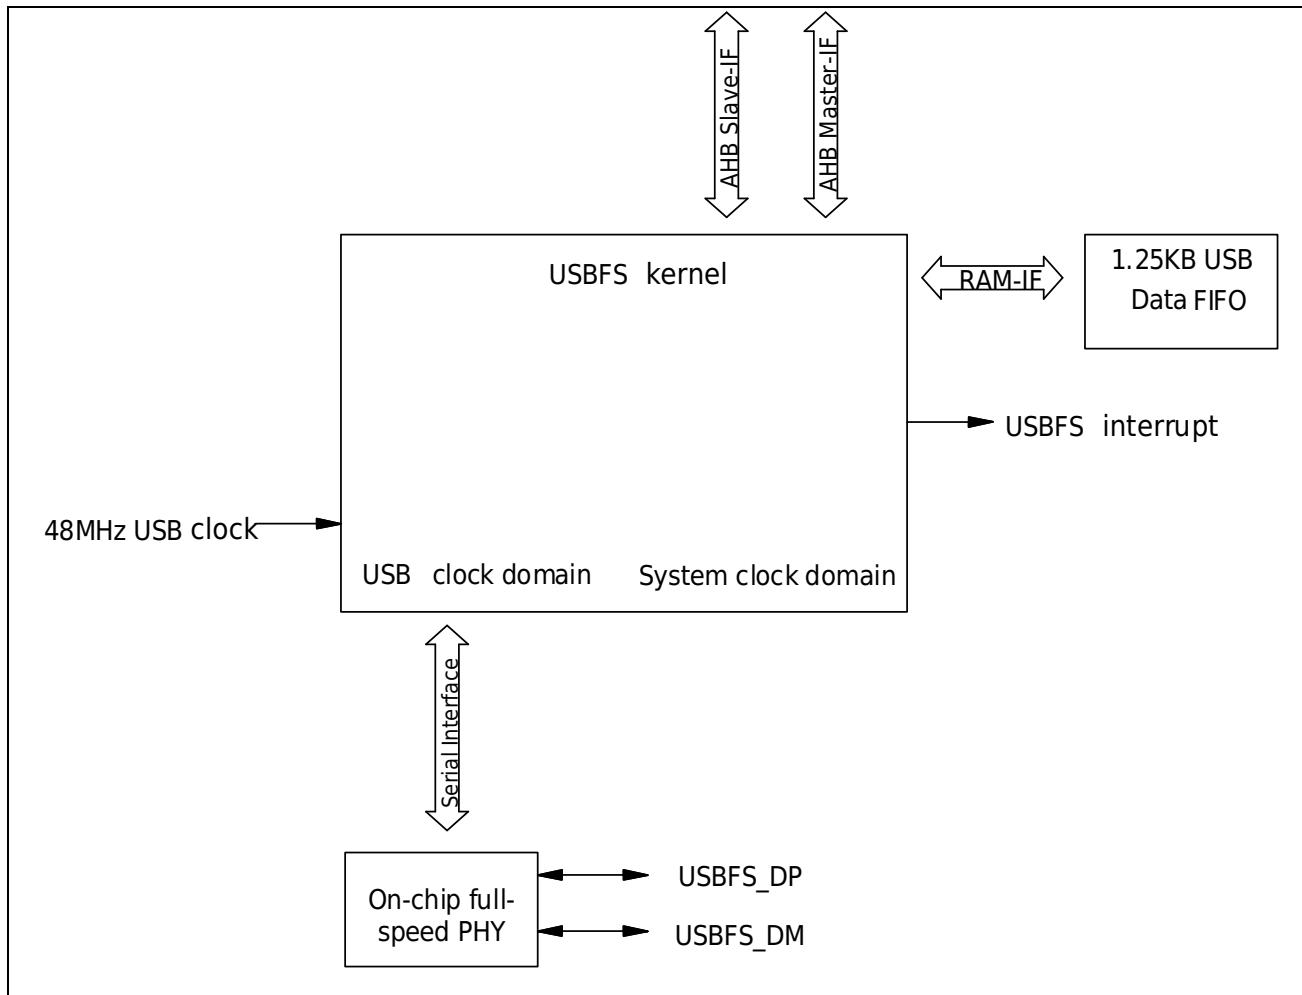

Figure 25-1 USBFS System Block Diagram

25.4 USBFS pin description

Table 25-1 USBFS Pin Descriptions

Pin name	Direction	Functional description
USBFS_DP	Input/Output	Differential data D+ signal
USBFS_DM	Input/Output	Differential Data D-Signal

Since the USBFS_DP and USBFS_DM pins are multiplexed with general GPIO, when using USBFS, it is recommended to turn off the digital function of the corresponding pins. For details, please refer to the Port Controller (GPIO) chapter. In addition, when the USBFS function is not in use, when the digital function pins corresponding to the USBFS_DP and USBFS_DM pins are flipped, additional current consumption will be generated.

25.5 USBFS function description

25.5.1 USBFS clock and working mode

The clock used by USBFS includes PHY clock and system clock. The PHY clock frequency needs to be configured as 48MHz. The 48MHz clock can be generated by the internal PLL circuit or by the internal high-speed 48M RC clock. Before using the USBFS module, it needs to be configured in the system controller module. Configure the USBFS clock inside.

USBFS is used as a device and includes an on-chip full-speed PHY.

Pull-up and pull-down resistors have been integrated inside the on-chip full-speed PHY, and USBFS can be automatically selected according to the current mode and connection status.

When USBFS is working, the VCC voltage range is 3.0~3.6V.

25.5.2 USBFS device capabilities

25.5.2.1 Introduction to device functions

A typical USB device mode system construction diagram is as follows:

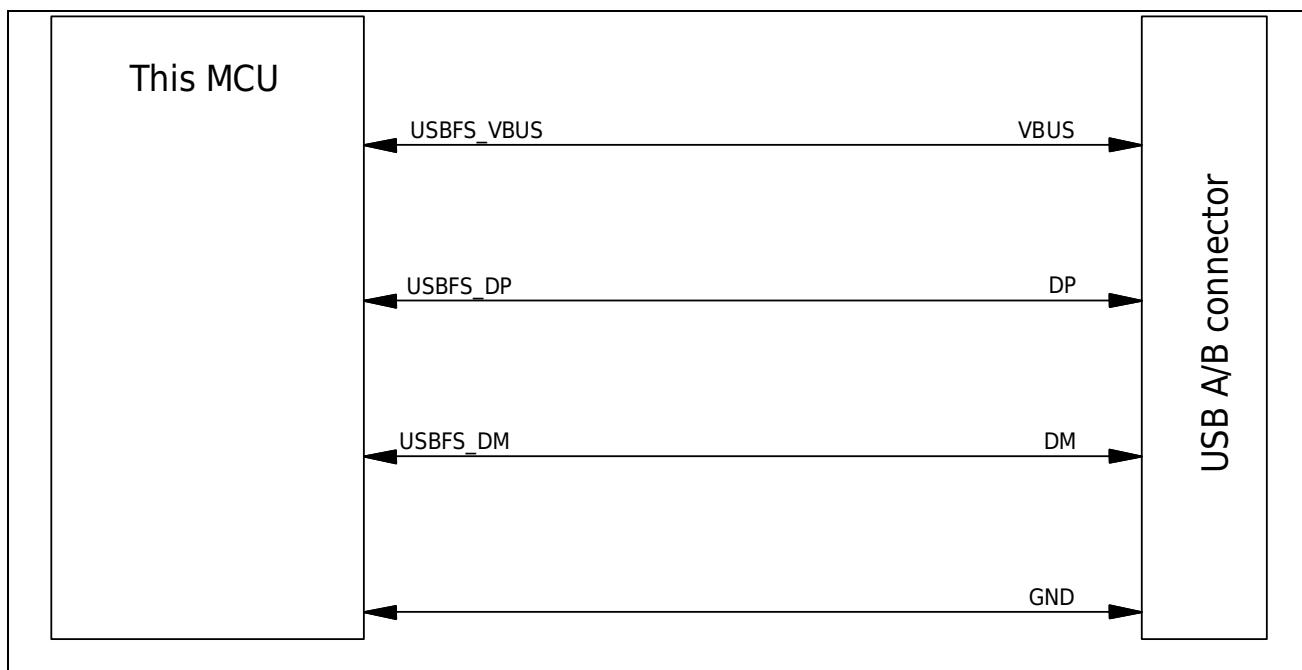

Figure 25-2 USBFS device mode system construction diagram

25.5.2.2 Device power status

When the module detects that USBFS_VBUS is high level, it will make the USB device enter the power supply state (see USB2.0 Section 9.1). Then, USBFS automatically connects the DP pull-up resistor, sends a signal that the full-speed device is connected to the host and generates a session request interrupt (VBUSVINT bit in USBFS_GINTSTS), indicating to enter the power supply state.

In the powered state, USBFS expects to receive a reset signal from the host. Other USB operations cannot be performed. As soon as the reset signal is received, a reset detected interrupt (USBRST in USBFS_GINTST) is generated. After the reset signal ends, an enumeration complete interrupt (ENUMDNE bit in USBFS_GINTSTS) will be generated, and USBFS will then enter the default state.

25.5.2.3 Device default state

By default, USBFS expects to receive a SET_ADDRESS command from the host. Other USB operations cannot be performed. When a valid SET_ADDRESS command is decoded on the USB, the application will write the corresponding address value to the device address field in the device configuration register (DAD bit in USBFS_DCFG). The USBF then enters the address state and is ready to answer host transactions with the configured USB address.

25.5.2.4 Device suspend state

The USBFS device continuously monitors USB activity. After the USB idle time reaches 3ms, an early suspend interrupt (ESUSP bit in USBFS_GINTSTS) will be issued, and the device will enter the suspend state confirmed by the suspend interrupt (USBSSUSP bit in USBFS_GINTSTS) after 3ms. Then, the device suspend bit in the device status register (SUSPSTS bit in USBFS_DSTS) is automatically set to 1, and USBFS then enters the suspend state.

Suspend can be exited through the device itself. In this case, the application will set the remote wakeup signal bit in the device control register (RWUSIG bit in USBFS_DCTL) to 1, and clear it to 0 within 1ms to 15ms.

However, if the device detects the resume signal sent by the host, it will generate a resume interrupt (WKUPINT bit in USBFS_GINTSTS), and the device suspend bit will be automatically cleared.

25.5.2.5 Device soft disconnect

The powered state can be exited by software with the soft-disconnect function. The DP pull-up resistor can be removed by setting the soft disconnect bit (SDIS bit in USBFS_DCTL) in the device control register to 1. At this time, although the USB cable is not actually pulled out from the host port, the device disconnection will still occur on the host side Detect interruption.

25.5.2.6 Device endpoint

Endpoint class

The USBFS module implements the following USB endpoints:

- Control endpoint 0:
 - Bi-directional and only handles control messages
 - Use a separate set of registers for IN and OUT transactions
 - Dedicated Control (USBFS_DIEPCTL0/ USBFS_DOEPCTL0) Register, Transport Configuration (USBFS_DIEPTSI0/ USBFS_DOEPTSI0) Register, and Status

Interrupt (USBFS_DIEPINT0/ USBFS_DOEPINT0) Register. The set of bits available in the control and transfer configuration registers is slightly different from the other endpoints

- 4 IN endpoints ($n = 1,3,5,7$)
 - Each endpoint can be configured to support isochronous, bulk, or interrupt transfer types
 - Each endpoint has dedicated control (USBFS_DIEPCTLn) registers, transfer configuration (USBFS_DIEPTSIZn) registers, and status interrupt (USBFS_DIEPINTn) registers
 - The device IN endpoint generic interrupt mask register (USBFS_DIEPMSK) can be used to enable/disable the same class of endpoint interrupt sources on all IN endpoints (including EP0)
 - Supports incomplete isochronous IN transfer interrupt (IISOIXFR bit in USBFS_GINTSTS), which will trigger when at least one transfer on an isochronous IN endpoint is incomplete in the current frame. This interrupt is triggered together with the periodic frame interrupt (USBFS_GINTSTS/EOPF)
- 4 OUT endpoints ($n = 2,4,6,8$)
 - Each endpoint can be configured to support isochronous, bulk, or interrupt transfer types
 - Each endpoint has dedicated control (USBFS_DOEPCTLn) registers, transfer configuration (USBFS_DOEPTSIZn) registers, and status interrupt (USBFS_DOEPINTn) registers
 - The device OUT endpoint general interrupt mask register (USBFS_DOEPMASK) can be used to enable/disable the same type of endpoint interrupt source on all OUT endpoints (including EP0)
 - Support for incomplete isochronous OUT transfer interrupts (INCOMPISOOUT bit in USBFS_GINTSTS), which will trigger when at least one transfer on an isochronous OUT endpoint is incomplete in the current frame. This interrupt is triggered together with the periodic frame interrupt (USBFS_GINTSTS/EOPF)

endpoint control

The application can take the following control over the endpoint through the device endpoint n IN/OUT control register (DIEPCTLn/DOEPCTLn):

- Endpoint enable/disable
- Activate the endpoint under the current configuration
- Set USB transfer type (isochronous, bulk and interrupt)
- Set the supported packet size
- Sets the Tx-FIFO number associated with the IN endpoint
- Set the data0/data1 PID you want to receive or use when sending (bulk/interrupt transfers only)
- Set the odd/even frame for receiving or sending transactions (only for synchronous transfers)
- The NAK bit can be set, so that regardless of the state of the FIFO at this time, a NAK is replied to the host's request

- The STALL bit can be set so that the host's tokens for this endpoint are all replied to STALL by the hardware
- The OUT endpoint can be set to listen mode, that is, no CRC check is performed on the received data

Endpoint transport

The Device Endpoint n Transfer Size registers (DIEPTSIZn/DOEPTSIZn) allow applications to program transfer size parameters and read transfer status. Setting this register must be done before setting the Endpoint Enable bit in the Endpoint Control register. After the endpoint is enabled, these fields become read-only immediately, and the USBFS module updates these fields according to the current transmission status.

The following transfer parameters can be programmed:

- Transfer size in bytes
- The number of packets that make up the entire transfer

Endpoint Status/Status

The Device Endpoint n Interrupt Registers (DIEPINTn/DOEPINTn) indicate the status of the endpoint on USB and AHB related events. When the OUT endpoint interrupt bit or the IN endpoint interrupt bit (OEPINT bit in USBFS_GINTSTS or IEPINT bit in USBFS_GINTSTS, respectively) is set in the module interrupt register, the application must read these registers for detailed information. Before an application can read these registers, it must first read the Device Overall Endpoint Interrupt (USBFS_DAINT) register to obtain the endpoint number of the device endpoint n interrupt register. The application must clear the corresponding bits in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

- The module provides the following status checking and interrupt generation functions:
 - Transfer complete interrupt, indicating to the application that both the AHB and the USB side have completed the data transfer
 - Setup phase completed (only for OUT endpoints of control transfer type)
 - The associated transmit FIFO is half empty or fully empty (IN endpoint)
 - A NAK reply has been sent to the host (IN endpoint for isochronous transfers only)
 - IN token received while TxFIFO is empty (only for IN endpoints of bulk and interrupt transfer types)
 - OUT token received when the endpoint has not been enabled
 - babble error detected
 - Application shutdown endpoint takes effect
 - The application sets NAK on the endpoint to take effect (only for the IN endpoint of the synchronous transmission type)
 - Received more than 3 consecutive setup packets (only for control type OUT endpoints)

- A timeout condition was detected (only for IN endpoints of control transfer type)
- Packets of isochronous transfer type are lost without generating an interrupt

25.5.3 USBFS power control

When the USBFS module is not used, the HCLK and PHY clocks of the USBFS module can be stopped by the system controller module to reduce power consumption.

Power reduction techniques can be used in the USB suspend state when the USB module is used but the device USB session is not started or the device is not connected.

- Stop the PHY clock (STPPCLK bit in USBFS_GCCTL)

Most of the 48 MHz internal clock domains of the USBFS full-speed module are clock-gated off when the Stop PHY Clock bit in the Clock-Gating Control Register is set to 1. Even if the application still provides the clock input, it will save the dynamic power consumption of the module due to the flipping of the clock signal. It will also turn off most of the units of the transceiver, and only the part responsible for detecting an asynchronous recovery event or a remote wake-up event will remain active. .

- HCLK gating (GATEHCLK bit in USBFS_GCCTL)

When the GATEHCLK bit in the Clock Gating Control Register is set to 1, most of the system clock domains inside the USBFS module are clock-gated off. Only the register read and write interfaces remain active. Even if the application still provides the clock input, it will save the module's dynamic power consumption due to the clock signal flipping.

To save dynamic power, the USB data FIFO is only clocked when it is accessed by the USBFS module.

25.5.4 USBFS data FIFO

The USBFS system has 1.25KB dedicated RAM and adopts an efficient FIFO control mechanism. The packet FIFO controller module in the USBFS module divides the RAM space into an aperiodic TxFIFO, a periodic TxFIFO (the application program pushes data into it for short-term storage before USB transmission) and an RxFIFO (data received from the USB is stored there briefly before being read by the application).

The aperiodic TxFIFO is shared by all aperiodic IN endpoints, and the RxFIFO is shared by all OUT endpoints. The sizes of the FIFOs are all software configurable to better meet application requirements.

25.5.5 USBFS device FIFO architecture

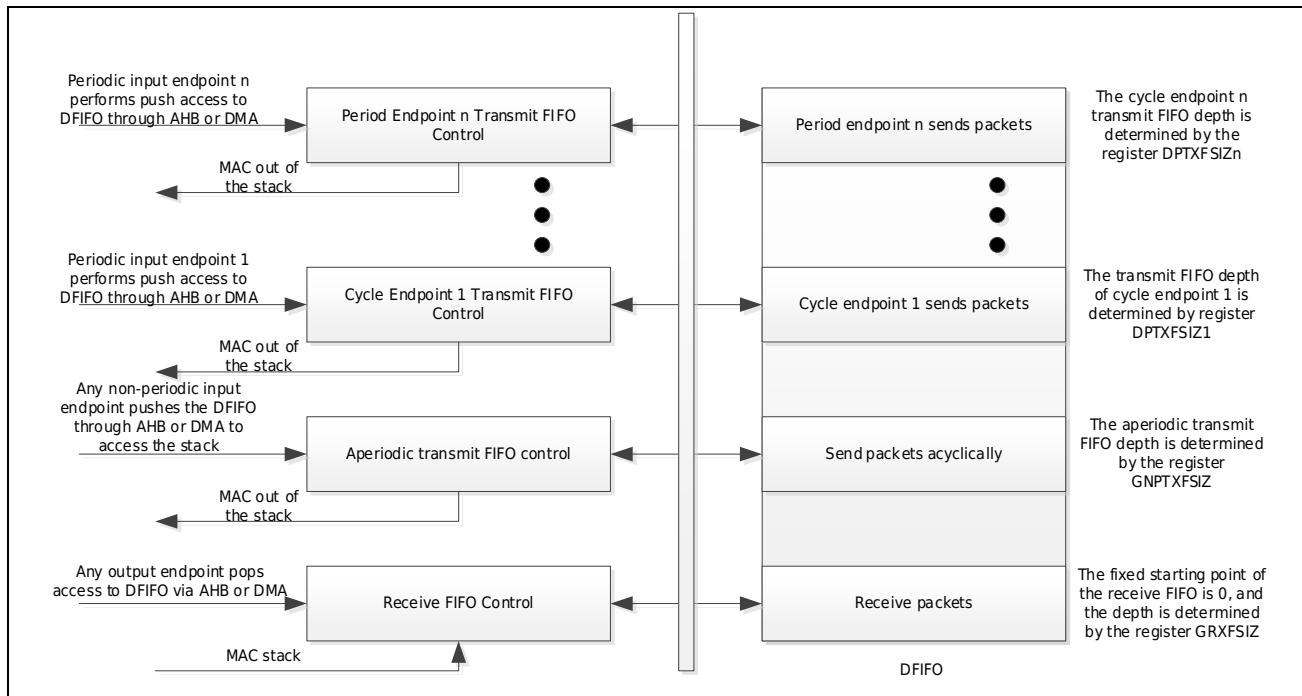

Figure 25-3 Schematic diagram of FIFO architecture in USBFS device mode

25.5.5.1 Device RxFIFO

USBFS devices use a single receive FIFO to receive data sent to all OUT endpoints. As long as there is free space in the Rx FIFO, the received data packets are filled into the Rx FIFO one by one. In addition to valid data, received packet status (containing OUT endpoint destination number, byte count, data PID, and validation of received data) is also stored by the module. When no space is available, the device replies with a transaction NAK to the host and triggers an interrupt on the addressed endpoint. The size of the receive FIFO is configured in the receive FIFO size register (GRXFSIZ).

A single receive FIFO architecture enables the USB device to more efficiently fill the receive RAM buffer:

- All OUT endpoints share the same RAM buffer (shared FIFO)
- The USBFS module can fill the receive FIFO to the limit for any host serial OUT token

The application will always receive the Rx FIFO not empty interrupt (RXFNE bit in USBFS_GINTSTS) as long as at least one packet is available for reading in the Rx FIFO. The application program reads the packet information from the receive status read and stack register (GRXSTSP), and finally reads the corresponding data from the receive FIFO by reading the stack address related to the endpoint.

25.5.5.2 DeviceTxFIFO

All non-periodic IN endpoints share one Tx FIFO. A Tx FIFO is exclusive to the cycle IN endpoint. The application configures the FIFO size for the aperiodic IN endpoint through the aperiodic transmit

FIFO size register (USBFS_GNPTXFSIZ); configures the FIFO size for the periodic IN endpoint n through the periodic IN endpoint transmit FIFO size register (DPTXFSIZn).

25.5.6 USBFS FIFO RAM allocation

Receive FIFO RAM allocation

The application should allocate RAM for SETUP packets: 11 slots must be reserved in the receive FIFO to receive SETUP packets on the control endpoint. The USBFS module will not write any other data to these locations reserved for SETUP packets. A location will be allocated for the global OUT NAK. Status information is written to the FIFO with each received packet. Therefore, at least (maximum packet size/4)+1 space must be allocated for received packets. If multiple isochronous endpoints are enabled, the space allocated for receiving consecutive packets must be at least twice (maximum packet size/4)+1. Usually, the recommended space is twice the size of (maximum packet/4 + 1), so that when the previous packet is sent to the CPU, the USB can receive subsequent packets at the same time.

The transfer completion status information is pushed into the FIFO along with the last packet received by this endpoint. In general, it is recommended to assign a location for each OUT endpoint.

Transmit FIFO RAM allocation

The minimum RAM space required for each IN endpoint's transmit FIFO is the maximum packet size for that particular IN endpoint.

25.5.7 USBFS system performance

With large RAM buffer, highly configurable FIFO size, fast 32-bit FIFO access via AHB push/pop registers, and especially advanced FIFO control mechanism for optimal USB and system performance. In fact, regardless of the current USB sequence, USBFS can efficiently fill the available RAM space through this mechanism. With these features:

- The application has enough margin to calculate and correct the CPU load to optimize CPU bandwidth utilization:
 - The application program can accumulate a large amount of sending data first, and then send it out via USB
 - Allows sufficient time margin to read data from the receive FIFO
- The USB module can keep working at full speed, that is, to provide the maximum full-speed bandwidth (as much hardware as possible to run automatically, and as little software as possible to participate)
 - The USB module can accumulate a large amount of sending data in advance at its disposal, so that the USB data sending can be autonomously managed
 - There is a lot of empty space in the receive buffer, which can be automatically filled with data from the USB

Because the USBFS module can efficiently fill the 1.25KB RAM buffer and 1.25KB send/receive data is enough to meet the amount of data that can be accommodated in a full-speed frame, the USB system can reach the maximum USB bandwidth within one frame without application program intervention.

25.5.8 USBFS interrupt and Events

The global interrupt is the main interrupt that the software needs to handle, and the flag bit of the global interrupt can be read in the USBFS_GINTSTS register.

Table 25-2 USBFS interrupt/Event Table

Interrupt logo	Description
WKUPINT	Remote Wakeup Interrupt
DATAFSUSP	Data fetch pending
INCOMPISOOUT	Incomplete OUT synchronous transfer
IISOIXFR	IN SYNC TRANSFER NOT COMPLETED
OEPINT	OUT endpoint interrupt
IEPINT	IN endpoint interrupt
EOPF	Periodic end-of-frame interrupt
ISOODRP	Drop sync OUT packet interrupt
ENUMDNE	Enumeration complete
USBRST	USB reset interrupt
USBSUSP	USB suspend interrupt
ESUSP	Early hang interrupt
GONAKEFF	Global OUT NAK active interrupt
GINAKEFF	Global aperiodic IN NAK active interrupt
RXFNE	RxFIFO not empty interrupt
SOF	Start of frame interrupt
MMIS	Pattern mismatch interrupt

25.6 USBFS programming model

25.6.1 USBFS module initialization

The work of the USBFS module requires two clocks, the system clock and the PHY clock, and the PHY clock frequency must be configured as 48Mhz. PHY clock can choose PLL clock or internal high-speed RC48M clock.

1. Configure the PLL clock or RC48M clock, and wait for the clock output to be stable (for the operation process, please refer to the chapter of the System Controller (SYSCTRL)).
2. Configure the system controller register SYSCTRL1.USB48MSEL, set 0 to select the RC48M clock, and set 1 to select the PLL clock.

3. Configure the system controller register PERI_CLKEN1.USB to set 1 to enable the USBFS module clock.

25.6.2 USBFS device initialization

An application must perform the following steps to initialize the module as a device.

1. In Slave mode, USBFS_GINTMSK.NPTxFEmpMsk and USBFS_GINTMSK.RxFLvlMsk are set to 1, in DMA mode, USBFS_GINTMSK.NPTxFEmpMsk and USBFS_GINTMSK.RxFLvlMsk are set to 0
2. Program the following fields in the USBFS_DCFG register:
 - Device Speed (DevSpd)
 - Non-zero length status output handshake signal (NZStsOUTHShk)
 - Period frame interval (PerFrInt)
3. Clear the USBFS_DCTL.SftDiscon bit to let the controller perform the connection to the master.
4. Program the USBFS_GINTMSK register to unmask the following interrupts:
 - USB reset (USBRstMsk)
 - Enumeration Done (EnumDoneMsk)
 - Early Suspend (ErlySuspMsk)
 - USB Suspend (USBSuspMsk)
 - SOF(SofMsk)
5. Wait for USBFS_GINTSTS.USBRst interrupt. This indicates that a reset signal has been detected on the USB, and the reset process lasts about 10ms from the reception of this interrupt. The application must perform the steps listed in the section Endpoint initialization on USB reset.
6. Wait for the USBFS_GINTSTS.EnumDone interrupt. This interrupt signals the end of the reset process on the USB. When this interrupt is received, the application must read the USBFS_DSTS register to determine the enumeration speed and perform the steps listed in USB enumeration completes.

At this point, the device is ready to accept SOF packets and perform control transfers on control endpoint 0.

25.6.3 USBFS device soft disconnect operation

The application program can set the register USBFS_DCTL.SftDiscon to perform a soft disconnect operation. When the device is in data transfer state, perform the following steps:

1. Set register USBFS_DCTL.SftDiscon
2. Set register USBFS_GRSTCTL.CSftRst
3. Wait for register USBFS_GRSTCTL.CSftRst bit to be cleared by controller
4. Re-execute the USBFS device initialization steps

25.6.4 Endpoint initialization on USB reset

1. Set all output endpoints NAK bits to 1
`USBFS_DOEPCTLn.SNAK = 1` (for all output endpoints)
 2. Unmask the following interrupt bits
`USBFS_DAINTMSK.INEP0=1` (control 0 input endpoint)
`USBFS_DAINTMSK.OUTEP0=1` (Control 0 output endpoint)
`USBFS_DOEPMSKn.SetUPMsk=1`
`USBFS_DOEPMSKn.XferComplMsk=1`
`USBFS_DIEPMSKn.XferComplMsk=1`
`USBFS_DIEPMSKn.TimeOUTMsk=1`
 3. Set data FIFO RAM for each FIFO
Program the `USBFS_GRXFSIZ` register to be able to receive output data and SETUP data for control transfers. This register value must be at least equal to 1 maximum packet size for Control Endpoint 0 + 2 words (for the state of the control output packet) + 10 words (for the SETUP packet).
Program the `USBFS_GNPTXFSIZ` register to be able to send control input data. This register value must be at least equal to 1 maximum packet size for Control Endpoint 0.
 4. Program the following fields in the endpoint-associated registers to control output endpoint 0 to receive SETUP packets.
 - `USBFS_DOEPTSIZ0.SUPCn=3` (receive up to 3 consecutive SETUP packets)
 - DMA mode, the `USBFS_DOEPDMA0` register specifies the memory address to store the received SETUP data packet
- At this point, all initialization required to receive the SETUP packet is complete.

25.6.5 USB enumeration completes

1. After the enumeration complete interrupt (`USBFS_GINTSTS.EnumDone`) occurs, the register `USBFS_DSTS.EnumSpd` is read to determine the enumeration speed of the device.
2. Program the MPS field in `USBFS_DIEPCTL0` to set the maximum packet size. This step configures control endpoint 0. The maximum packet size for the control endpoint depends on the enumeration speed.
3. DMA mode, programming the `USBFS_DOEPCTL0` register enables control of output endpoint 0.
`USBFS_DOEPCTL0.EPEna = 1`
At this point, the device is ready to receive SOF packets and is configured to perform control transfers on control endpoint 0.

25.6.6 Endpoint initialization when a SetAddress command is received

This section describes what an application must do when it receives a SetAddress command in a SETUP packet.

1. Program the USBFS_DCFG register with the device address received in the SetAddress command.
2. Program the block to emit input packets for the status phase.

25.6.7 Endpoint initialization when a SetConfiguration/SetInterface command is received

This section describes what an application must do when it receives a SetConfiguration or SetInterface command in a SETUP packet.

1. When the SetConfiguration command is received, the application must program the endpoint registers to configure them with the characteristics of valid endpoints in the new configuration.
2. When a SetInterface command is received, the application must program the endpoint registers specified by the command.
3. An endpoint that was valid in a previous configuration or other setup is not valid in a new configuration or other setup. These invalid endpoints must not be activated.
4. Use the USBFS_DAINTMSK register to enable interrupts for valid endpoints and mask interrupts for invalid endpoints.
5. Set data FIFO RAM for each FIFO.
6. After configuring all required endpoints, the application must program the module to send input packets for the status phase.

At this point, the device module is ready to receive and send any type of data packet

25.6.8 Endpoint activation (Active)

This section describes the steps required to activate a device endpoint or configure an existing device endpoint to a new type.

1. Program the characteristics of the desired endpoint in the following fields of the USBFS_DIEPCTL_n register (for input endpoints) or the USBFS_DOEPCTL_n register (for output endpoints).
 - Maximum Packet Size (MPS)
 - USB active endpoint bit (USBActEP) set
 - Endpoint Initial Data Synchronization Bit (DPID) (for interrupt and bulk endpoints)
 - Endpoint type (EPType)
 - TxFIFO number (TxFNum)
2. Once the endpoint is activated, the module starts decoding tokens sent to the endpoint and

replies with a valid handshake if the received token is valid.

25.6.9 Endpoint inactive (Deactive)

This section describes the steps required to deactivate existing endpoints.

1. In the endpoint to be deactivated, clear the USB active endpoint bit (USBActEP) in the USBFS_DIEPCTLn register (for input endpoints) or USBFS_DOEPCTLn register (for output endpoints) to 0.
2. When an endpoint is deactivated, the module ignores tokens sent to it, causing a USB timeout.

25.6.10 Disable (Disable) output endpoint

The application must follow the steps below to disable an enabled output endpoint.

1. USBFS_DCTL.SGOUTNak=1, enter the global output endpoint NAK mode
2. Waiting for interrupt USBFS_GINTSTS.GOUTNakEff
3. USBFS_DOEPCTLn.EPDDisable=1, USBFS_DOEPCTLn.SNAK=1
4. Wait for interrupt USBFS_DOEPINTx.EPDIsbld,
When an interrupt occurs, the controller clears the following registers
USBFS_DOEPCTLx.EPDis = 0
USBFS_DOEPCTLn.EPEna = 0
5. The program must exit the global output endpoint NAK mode
USBFS_DCTL.CGOUTNak = 1
USBFS_DCTL.SGOUTNak=0

25.6.11 Pause (Stall) asynchronous output endpoint

Applications must follow the steps below to suspend an asynchronous output endpoint.

1. USBFS_DCTL.SGOUTNak=1, enter the global output NAK mode
2. Waiting for interrupt USBFS_GINTSTS.GOUTNakEff
3. USBFS_DOEPCTLn.EPDDisable=1, USBFS_DOEPCTLn.Stall=1
4. Wait for interrupt USBFS_DOEPINTx.EPDIsbld,
When an interrupt occurs, the controller clears the following registers
USBFS_DOEPCTLx.EPDis = 0
USBFS_DOEPCTLn.EPEna = 0
5. The program must exit the global output endpoint NAK mode
USBFS_DCTL.CGOUTNak = 1
USBFS_DCTL.SGOUTNak=0

25.6.12 Global output endpoint NAK mode

The program must enter the global output endpoint NAK mode to stop receiving any data in the receive FIFO.

1. USBFS_DCTL.SGOUTNak=1, enter the global output NAK mode.
2. Waiting for the interrupt USBFS_GINTSTS.GOUTNakEff, when an interrupt occurs, it means that the controller has stopped receiving data other than SETUP packets.
3. The program can write the register to mask this interrupt USBFS_GINTMSK.GOUTNakEffMsk=0.
4. If the program wants to exit the global output NAK mode, perform the following operations to clear the interrupt at the same time.

USBFS_GINTSTS.GOUTNakEff

USBFS_DCTL.CGOUTNak = 1

USBFS_DCTL.SGOUTNak=0

25.6.13 Output endpoint transmission stopped

1. Enable all output endpoints USBFS_DOEPCTLn.EPEna = 1.
2. Wait for USBFS_GRSTCTL.AHBIdle to be set, indicating that the AHB bus controller of the controller is idle.
3. USBFS_GRSTCTL.RxFFIsh =1
4. Wait for USBFS_GRSTCTL.RxFFIsh to be cleared, indicating that the receive FIFO is successfully emptied.
5. Execution section Disable (Disable) output endpoint.

25.6.14 Configure the interrupt input endpoint as a periodic or aperiodic endpoint (shared FIFO mode)

In the shared FIFO mode, the interrupt input endpoint can be configured as a periodic input endpoint or an aperiodic input endpoint by setting the value of USBFS_DIEPCTLn.TxFNum.

When configured as an acyclic input endpoint, the program must follow the operation flow of the acyclic input endpoint.

When configured as a periodic input endpoint, the program must follow the operation flow of the periodic input endpoint.

25.6.15 Global aperiodic input endpoint NAK mode (shared FIFO mode)

1. Set USBFS_DCTL.SGNPInNak=1 to notify the controller to stop sending data to the aperiodic input endpoint and enter the global aperiodic input endpoint NAK mode.
2. Waiting for the interrupt flag USBFS_GINTSTS.GINNakEff to be set, the flag is set to indicate that the controller has stopped sending data to the non-periodic input terminal, but the controller can still send data to the non-periodic input terminal before it is set.
3. The interrupt flag USBFS_GINTSTS.GINNakEff can be set by
USBFS_GINTMSK.GINTNakEffMsk mask,
Set USBFS_GINTMSK.GINTNakEffMsk=0,
Shield interrupt flag USBFS_GINTSTS.GINNakEff
Set USBFS_GINTMSK.GINTNakEffMsk=1,
Unmask interrupt flag USBFS_GINTSTS.GINNakEff
4. programming USBFS_DCTL.CGNPInNak=1
USBFS_DCTL.SGNPInNak=0 ,
To exit the global aperiodic input endpoint NAK mode,
At the same time clear the interrupt flag USBFS_GINTSTS.GINNakEff.

25.6.16 NAK occurred

1. To stop sending data to a particular input endpoint, the program must set the NAK bit USBFS_DIEPCTLn.SNAK=1, enter the input endpoint NAK mode.
2. Wait for the interrupt flag bit USBFS_DIEPINTn.NAKIntrpt to be set, indicating that the controller has stopped sending data to this endpoint.
3. USBFS_DIEPMSK.NAKMsk = 0, can mask interrupt USBFS_DIEPINTn.NAKIntrpt,
USBFS_DIEPMSK.NAKMsk = 1, unmask interrupt USBFS_DIEPINTn.NAKIntrpt.
4. If you want to exit the input endpoint NAK mode
USBFS_DIEPCTLn.CNAK=1

25.6.17 Disable non-periodic input endpoints (Shared FIFO mode)

Disable endpoint operation must be after the endpoint is enabled. To disable an aperiodic input endpoint, the program must disable all aperiodic endpoints.

1. Set USBFS_DCTL.SGNPInNak=1 to enter the global aperiodic input endpoint NAK mode.
2. Wait for the interrupt flag bit USBFS_GINTSTS.GINNakEff to be set.
3. Set USBFS_DIEPCTLn.EPDis=1, USBFS_DIEPCTLn.SNAK=1, one after the other, until all aperiodic endpoints are disabled.
4. Wait for the interrupt flag bit USBFS_DIEPINTn.EPDisbld to be set, which indicates that the controller has disabled the corresponding endpoint, and clear the register bits USBFS_DIEPCTLn.EPEna and USBFS_DIEPCTLn.EPDis at the same time. It is judged in turn that all non-periodic endpoints have been disabled.

5. The program must read the values of all disabled non-periodic input endpoint registers USBFS_DIEPTSI n , and calculate the amount of data that each endpoint has transferred.
6. The program must clear the aperiodic send FIFO, the operation is as follows:
USBFS_GRSTCTL.TxFNum=0
USBFS_GRSTCTL.TxFFlsh=1
Wait for the controller to clear USBFS_GRSTCTL.TxFFlsh, Indicates that aperiodic transmit FIFO clearing has ended.
7. Program USBFS_DCTL.CGNPInNak=1 USBFS_DCTL.SGNPInNak=0, exit the global aperiodic input endpoint NAK mode.

25.6.18 Disable cycle input endpoint (Shared FIFO mode)

Disable endpoint operation must be after the endpoint is enabled.

1. Set USBFS_DIEPCTL n .SNAK=1,
Wait for the interrupt flag bit USBFS_DIEPINT n .INEPNakEff to be set,
This flag bit is set to indicate that the controller has stopped sending data to this endpoint.
2. Set USBFS_DIEPCTL n .EPDis=1,
Wait for the interrupt flag bit USBFS_DIEPINT n .EPDisbld to be set,
The flag bit is set to indicate that the controller has disabled the corresponding endpoint,
and the register bit is cleared at the same time
USBFS_DIEPCTL n .EPEna 和 USBFS_DIEPCTL n .EPDis。
3. The program must read the value of the disabled cycle input endpoint register USBFS_DIEPTSI n , and calculate the amount of data that the endpoint has transferred.
4. The program must clear the aperiodic send FIFO, the operation is as follows:
USBFS_GRSTCTL.TxFNum= Periodic FIFO Number
USBFS_GRSTCTL.TxFFlsh=1
Wait for the controller to clear USBFS_GRSTCTL.TxFFlsh, Indicates that periodic transmit FIFO clearing has ended.

25.6.19 Aperiodic input data transfer timeout (shared FIFO mode)

1. When an aperiodic input endpoint is transmitting data,
The interrupt flag bit USBFS_DIEPCTL n .TimeOut is set, and the flag bit is set to indicate that the data transmission of the endpoint has timed out.
2. Follow the steps to Disable non-periodic input endpoints (Shared FIFO mode).
3. Re-enable the endpoint and transmit timed-out packets.

25.6.20 Non-synchronous input endpoint pause (shared FIFO mode)

1. Set USBFS_DCTL.SGNPInNak=1 to enter the global aperiodic input endpoint NAK mode.
2. Wait for the interrupt flag bit USBFS_GINTSTS.GINNakEff to be set.

3. Set USBFS_DIEPCTLn.EPDis=1, USBFS_DIEPCTLn.Stall=1, one after the other, until all aperiodic endpoints are disabled.
4. Wait for the interrupt flag bit USBFS_DIEPINTn.EPDisbld to be set, which indicates that the controller has disabled the corresponding endpoint, and clear the register bits USBFS_DIEPCTLn.EPEna and USBFS_DIEPCTLn.EPDis at the same time. It is judged in turn that all non-periodic endpoints have been disabled.
5. The program must read the values of all disabled non-periodic input endpoint registers USBFS_DIEPTSIzn, and calculate the amount of data that each endpoint has transferred.
6. The program must clear the aperiodic send FIFO, the operation is as follows:
`USBFS_GRSTCTL.TxFNum=0`
`USBFS_GRSTCTL.TxFFlsh=1`
Wait for the controller to clear USBFS_GRSTCTL.TxFFlsh, indicating that the aperiodic transmit FIFO clearing has ended.
7. Set USBFS_DCTL.SGNPInNak=0 to exit the global aperiodic input endpoint NAK mode.
8. Re-enable other endpoints that do not need to be suspended
9. To exit suspend mode, set USBFS_DIEPCTLn.Stall=0.

25.6.21 Input endpoint transfer stop (shared FIFO mode)

1. Set USBFS_DIEPCTLn.EPDis=1.
2. Wait for the interrupt flag bit USBFS_DIEPINTn.EPDisbld to be set, which indicates that the controller has disabled the corresponding endpoint, and clear the register bits DIEPCTLn.EPEna and DIEPCTLn.EPDis at the same time.
3. The program must clear the aperiodic send FIFO, the operation is as follows:
`USBFS_GRSTCTL.TxFNum=0`
`USBFS_GRSTCTL.TxFFlsh=1`
Wait for the controller to clear USBFS_GRSTCTL.TxFFlsh, Indicates that aperiodic transmit FIFO clearing has ended.

25.6.22 Endpoint mismatch (shared FIFO mode)

In the shared FIFO mode, all non-periodic input endpoints share one transmit FIFO, and the program must predict the order in which the master accesses the non-periodic input endpoints. When the sequence prediction is wrong, an endpoint mismatch will occur, and the interrupt flag USBFS_DIEPINTn.INTknEPMis will be set. .

25.6.23 Control transfer

There are three types of control transfers:

- Control write transfer
- Control read transfer

- Two-Phase Control Transfer

Each control transfer consists of two or three phases:

- Setup stage
- Data stage
- Status stage

25.6.23.1 Controlling the Write Transfer Programming Flow

Control write transfer Setup phase

1. Create a cache in system memory to hold Setup packets
2. Program register USBFS_DOEPDMA0 to configure the base address of the cache list
3. XferSize, PktCnt and SUPCnt fields of programming register USBFS_DOEPTSIZ0
4. The programming register USBFS_DOEPCTL0.MPS is used to configure the maximum packet size of the control endpoint, and the programming register USBFS_DOEPCTL0.EPEna is set to 1 to enable the control output endpoint
5. Waiting for an output endpoint interrupt
6. When the controller receives the Setup token packet, it will set the USBFS_DOEPINT0 interrupt
 - a) If USBFS_DOEPINT0.XferComp=1 and USBFS_DOEPINT0.SetUp=0, the program must read the StupPktRcvd bit of the register USBFS_DOEPINT0. If StupPktRcvd=1, it means that the Setup token package has been received. The program must decode the type of control transfer sent by the master. Then the program must check whether USBFS_DOEPINT0.StsPhaseRcvd is set to 1, if it is set to 1, it means entering the status phase, if it is not set to 1, it means entering the data phase.
 - b) If USBFS_DOEPINT0.XferComp=1 and USBFS_DOEPINT0.SetUp=1, the program must read the StupPktRcvd bit of the USBFS_DOEPINT0 register. If StupPktRcvd=1, it means that the Setup token package has been received. The program must decode the type of control transfer sent by the master. Then the program must enter the data phase. USBFS_DOEPINT0.SetUp=1 indicates that the master sent an output token packet during the data phase of the control write transfer.

Controlling the write transfer data phase

1. Create n buffers to receive `wlength` bytes of data Make sure each buffer contains a packet [$n=wlength/MPS+wlengthMOD(MPS)$]
2. Program register USBFS_DOEPDMA0 to configure the base address of the descriptor list
3. XferSize, PktCnt and SUPCnt fields of programming register USBFS_DOEPTSIZ0
4. The programming register USBFS_DOEPCTL0.MPS is used to configure the maximum packet size of the control endpoint, and the programming register USBFS_DOEPCTL0.EPEna is set to 1 to enable the control output endpoint

5. Waiting for an output endpoint interrupt
6. Depending on the type of token received, the controller will generate the following interrupts
 - a) If USBFS_DOEPINT0.XferComp=0 and USBFS_DOEPINT0.SetUp=1, the controller replies NAK to the first output token sent by the master. Then program USBFS_DOEPCTL0.CNAK=1 to clear NAK, and then jump to step 4.
 - b) If USBFS_DOEPINT0.XferComp=1 and USBFS_DOEPINT0.SetUp=0, read the StupPktRcvd bit of the USBFS_DOEPINT0 register. If StupPktRcvd=0, it means that the output token has been received. If this token is not the last one, jump to step 4 to receive the next one. token. If this is the last token, configure USBFS_DOEPCTL0.Stall=1, so that the controller will suspend receiving the output token packet sent by the master. The data phase is complete and the program will jump to the status phase which controls the write transfer. If StupPktRcvd=1, it indicates that a new control transfer Setup token has been received. The program must decode the type of control transfer sent by the master.
 - c) If USBFS_DOEPINT0.XferComp=1 and USBFS_DOEPINT0.StsPhseRcvd=1, the interrupt flag USBFS_DOEPINT0.XferComp indicates that the controller received an output token during the data phase and the interrupt flag USBFS_DOEPINT0.StsPhseRcvd indicates the start of the status phase. After the last output token has been processed, the program enters the status phase which controls the write transfer.

Controlling the write transfer status phase

1. Create a buffer list in system memory containing an input buffer
2. Program register USBFS_DIEPDMA0 to configure the base address of the cache list
3. XferSize, PktCnt field of programming register USBFS_DIEPTSIZ0
4. The programming register USBFS_DIEPCTL0.MPS is used to configure the maximum packet size of the control endpoint, and the programming register USBFS_DIEPCTL0.EPEna is set to 1 to enable the control input endpoint
5. Create a buffer list in system memory containing an output buffer
6. Program register USBFS_DOEPDMA0 to configure the base address of the cache list
7. XferSize, PktCnt and SUPCnt fields of programming register USBFS_DOEPTSIZ0
8. The programming register USBFS_DOEPCTL0.MPS is used to configure the maximum packet size of the control endpoint, and the programming register USBFS_DOEPCTL0.EPEna is set to 1 to enable the control output endpoint
9. Wait for control endpoint input and output interrupts to occur at the same time
10. Depending on the type of token received, the controller will generate the following interrupts
If USBFS_DIEPINT0.XferComp=1, only the input endpoint generates an interrupt, indicating that the DMA has processed the zero-length data packet of the input descriptor and pushed it to the corresponding transmit FIFO. The status phase of the current control transfer is

complete and the program can process the next control transfer.

If USBFS_DOEPINT0.StsPhseRcvd=1, only the output endpoint generates an interrupt, program register USBFS_DIEPCTL0.CNAK=1, accept the input status token, and jump to step 8.

If USBFS_DOEPINT0.XferComp=1, only the output endpoint generates an interrupt, indicating that the master sends a new Setup token in advance.

If USBFS_DOEPINT0.SetUp=0 and USBFS_DOEPINT0.StupPktRcvd=1, it means that the new control transfer Setup token has been received. The program must decode the type of control transfer sent by the master. The program must then proceed to the next stage.

If USBFS_DOEPINT0.SetUp=1 and USBFS_DOEPINT0.StupPktRcvd=1, it means that the new control transfer Setup token has been received.

DOEPINT0.SetUp=1 indicates that the master may send the following token packets:

- Control write transfer data phase output token packet
- Controls the read transfer data phase input token packet
- Two-phase control transfer status phase input token packet

25.6.23.2 Controlling the read transfer programming flow

Control read transfer Setup phase

1. Create a buffer list in system memory containing an output buffer
2. Program register USBFS_DOEPDMA0 to configure the base address of the cache list
3. XferSize, PktCnt and SUPCnt fields of programming register USBFS_DOEPTSIZ0
4. The programming register USBFS_DIEPCTL0.MPS is used to configure the maximum packet size of the control endpoint, and the programming register USBFS_DIEPCTL0.EPEna is set to 1 to enable the control output endpoint
5. Waiting for an output endpoint interrupt
6. When the controller receives the Setup packet, it will set the USBFS_DOEPINT0 interrupt
 - a) If USBFS_DOEPINT0.XferComp=1 and USBFS_DOEPINT0.SetUp=0, the program must read the StupPktRcvd bit of the USBFS_DOEPINT0 register. If StupPktRcvd=1, it means that the Setup token has been received. The program must decode the type of control transfer sent by the master. The program must then enter the data phase of the control transfer.
 - b) If USBFS_DOEPINT0.XferComp=1 and USBFS_DOEPINT0.SetUp=1, the program must read the StupPktRcvd bit of the USBFS_DOEPINT0 register. If StupPktRcvd=1, it means that the Setup token has been received. USBFS_DOEPINT0.SetUp=1 indicates that the master sent an input token packet during the data phase of the control read transfer. The program must then proceed to the next stage.

Controls the read transfer data and status phase

1. Create n buffers to receive `wlength` bytes of data Make sure each buffer contains a packet [n=wlength/MPS+wlengthMOD(MPS)]

2. XferSize, PktCnt field of programming register USBFS_DIEPTSIZ0
3. Program register USBFS_DIEPDMA0 to configure the base address of the cache list
4. Programming register USBFS_DIEPCTL0.MPS to configure the maximum packet size of the control endpoint, programming the control input endpoint register USBFS_DIEPCTL0.EPEna to 1 to enable the control input endpoint
5. Program the XferSize, PktCnt and SUPCnt fields of register USBFS_DOEPTSIZ0 to receive an advanced status phase or a new Setup token packet.
6. Program register USBFS_DOEPDMA0 to configure the base address of the cache list
7. Programming register USBFS_DOEPCTL0.MPS to configure the maximum packet size of the control endpoint, programming register USBFS_DOEPCTL0.EPEna is set to 1 to enable the control output endpoint programming register USBFS_DOEPCTL0.CNAK=1 to clear NAK
8. Wait for the input and output interrupt of the control endpoint.
9. Depending on the type of token packet received by the controller, a combination of the following interrupts will be generated:
If USBFS_DOEPINT0.SetUp=1, and only the output endpoint generates an interrupt, it means that the master sends the input token to start the data phase of this transfer.
Program USBFS_DIEPCTL0.CNAK=1 to clear NAK and receive the input token packet of this transmission data stage. Program USBFS_DOEPCTL0.CNAK=1 to clear NAK and receive the output token packet in the status phase of this transmission or the SETUP token packet in the Setup phase. Skip to step 9.
If USBFS_DIEPINT0.XferComp=1, and only the input endpoint generates an interrupt, it means that the DMA has processed the input buffer data packet and pushed it to the corresponding transmit FIFO. When the last buffered XferCompl flag is generated, program USBFS_DIEPCTL0.Stall=1 to suspend responding to additional input token packets sent by the master when all data in the transmit FIFO has been sent to the master and the transmit FIFO is empty. Skip to step 9 and wait for the output endpoint interrupt. If USBFS_DOEPINT0.XferComp=1, and only the output endpoint generates an interrupt, it means that the master sends the status phase of the control transfer or a Setup token packet of a new control transfer.
 - a) If USBFS_DOEPINT0.XferComp=1 and USBFS_DOEPINT0.SetUp=0, the program must read the StupPktRcvd bit of the USBFS_DOEPINT0 register. If StupPktRcvd=1, it means that the Setup token has been received. The program must decode the type of control transfer sent by the master. If StupPktRcvd=0, it means that the output token of the status phase of this transmission has been received. The program must prepare a buffer for the next control transfer.
 - b) If USBFS_DOEPINT0.XferComp=1 and USBFS_DOEPINT0.SetUp=1, the program must read the StupPktRcvd bit of the USBFS_DOEPINT0 register. If StupPktRcvd=1, it means that the Setup token has been received. The program must decode the type of control transfer sent

by the master.

25.6.23.3 Two-Phase Control Transfer

Two-stage control transmission Setup stage

1. Create a buffer list in system memory containing an output buffer
2. XferSize, PktCnt and SUPCnt fields of programming register USBFS_DOEPTSIZ0
3. Program register USBFS_DOEPDMA0 to configure the base address of the cache list
4. The programming register USBFS_DOEPCTL0.MPS is used to configure the maximum packet size of the control endpoint, and the programming register USBFS_DOEPCTL0.EPEna is set to 1 to enable the control output endpoint
5. Waiting for an output endpoint interrupt
6. When the controller receives the Setup token packet, it will set the USBFS_DOEPINT0 interrupt
 - a) If USBFS_DOEPINT0.XferComp=1 and USBFS_DOEPINT0.SetUp=0, the program must read the StupPktRcvd bit of the USBFS_DOEPINT0 register. If StupPktRcvd=1, it means that the Setup token has been received. The program must decode the type of control transfer sent by the master. According to the Wlength field, the program can determine whether the current transfer is a two-phase control transfer. In the case of a two-phase control transfer, the program must enter the status phase of the transfer.
 - b) If USBFS_DOEPINT0.XferComp=1 and USBFS_DOEPINT0.SetUp=1, the program must read the StupPktRcvd bit of the USBFS_DOEPINT0 register. If StupPktRcvd=1, it means that the Setup token has been received. USBFS_DOEPINT0.SetUp=1 indicates that the master has sent an input token packet during the data phase of this control read transfer.

Two-phase control transfer status phase

1. Creates a buffer list in system memory containing an input buffer.
2. Program the XferSize, PktCnt fields of the USBFS_DIEPTSIZ0 register.
3. Program register USBFS_DIEPDMA0 to configure the base address of the cache list.
4. The programming register USBFS_DIEPCTL0.MPS is used to configure the maximum packet size of the control endpoint, and the programming register USBFS_DIEPCTL0.EPEna is set to 1 to enable the control output endpoint.
5. To program the output endpoint, create a buffer list in system memory containing an output buffer guaranteed to receive a new Setup token packet during the state phase.
6. Program the XferSize, PktCnt and SUPCnt words of register USBFS_DOEPTSIZ0.
7. Program register USBFS_DOEPDMA0 to configure the base address of the cache list.
8. The programming register USBFS_DOEPCTL0.MPS is used to configure the maximum packet size of the control endpoint, and the programming register USBFS_DOEPCTL0.EPEna is set to 1 to enable the control output.
9. Wait for the input and output interrupt of the control endpoint.

10. Depending on the type of token packet received by the controller, a combination of the following interrupts will be generated:
 - If USBFS_DOEPINT0.Setup=1, and only the output endpoint generates an interrupt, program USBFS_DIEPCTL0.CNAK=1 to clear NAK and receive the input token packet of this transfer status phase. Skip to step 8.
 - If USBFS_DIEPINT0.XferComp=1, only the input endpoint generates an interrupt, indicating that the DMA has processed the zero-length data packet in the input buffer and pushed it to the corresponding transmit FIFO. The two-phase control transfer is complete and the program can process a new control transfer.
 - If USBFS_DOEPINT0.XferComp=1, and only output endpoints generate interrupts.
- a) If USBFS_DOEPINT0.XferComp=1 and USBFS_DOEPINT0.SetUp=0, the program must read the StupPktRcvd bit of the USBFS_DOEPINT0 register. If StupPktRcvd=1, it means that the Setup token for the new control transfer has been received. The program must decode the type of control transfer sent by the master. The program must handle new control transfers.
- b) If USBFS_DOEPINT0.XferComp=1 and USBFS_DOEPINT0.SetUp=1, the program must read the StupPktRcvd bit of the USBFS_DOEPINT0 register. If StupPktRcvd=1, it means that the Setup token for the new control transfer has been received.
USBFS_DOEPINT0.SetUp=1 indicates that the master may send the following token packets:
 - Control write transfer data phase output token packet
 - Controls the read transfer data phase input token packet
 - Two-phase control transfer status phase input token packet

25.6.24 Output data transfer

25.6.24.1 Control Setup Transfer

1. Programming register USBFS_DOEPTSIZ0
USBFS_DOEPTSIZ0.SUPCnT = 3
2. Program register USBFS_DOEPDMA0 and register USBFS_DIEPCTL0 according to endpoint characteristics, and enable endpoint USBFS_DIEPCTL0.EPEna = 1
3. Wait for the USBFS_DOEPINT0.SETUP interrupt flag to be set to indicate that the SETUP data transfer is complete.
4. The program must read the register USBFS_DOEPTSIZ0 to determine the number of SETUP packets received and process the last received SETUP packet.
5. In DMA mode, the program must determine whether the register USBFS_DOEPINT0.Back2BackSETup is set. If set, indicates that the controller has received more than 3 back-to-back SETUP packets. In this case, the program must ignore the USBFS_DOEPTSIZ0.SUPCnT value and use the register USBFS_DOEPDMA0 to directly read the last received SETUP packet.

25.6.25 No threshold for acyclic bulk-in data transfer

1. XferSize and PktCnt fields of programming register USBFS_DIEPTSI_n, programming register USBFS_DIEPDMAn.
2. According to the endpoint characteristic programming register USBFS_DIEPCTL_n, set the CNAK bit and the EPEna bit.
3. In DMA mode, program the NextEp field to ensure that the controller fetches the input endpoint data in the correct order.
4. The USBFS_DIEPINT_n.TimeOut interrupt flag bit is set to indicate that a timeout condition has been detected on this endpoint. For the handling method, please refer to the chapter Aperiodic input data transfer timeout (shared FIFO mode).

25.6.26 Thresholds for acyclic bulk-in data transfers

1. XferSize and PktCnt fields of programming register USBFS_DIEPTSI_n, programming register USBFS_DIEPDMAn.
2. Program the register USBFS_DIEPCTL_n according to the endpoint characteristics, set the CNAK bit and the EPEna bit, and program the USBFS_DIEPCTL_n.TXFNum field.
3. The USBFS_DIEPINT_n.XferCompl interrupt flag bit is set to indicate the completion of an aperiodic input transfer. Read the XferSize and PktCnt fields of the register USBFS_DIEPTSI_n, the values are both 0, indicating that all data has been transferred.

25.6.27 Asynchronous output data transfer without threshold

1. XferSize and PktCnt fields of programming register USBFS_DOEPTSI_n, programming register USBFS_DOEPDMAn.
2. According to the endpoint characteristic programming register USBFS_DOEPCCTL_n, set the CNAK bit and the EPEna bit.
3. The USBFS_DOEPIINT_n.XferCompl interrupt flag bit is set to indicate the completion of an asynchronous output transfer. Read the register USBFS_DOEPTSI_n to determine the size of the received data packet.

25.6.28 Asynchronous output data transfers with threshold

For the operation process, please refer to the chapter Asynchronous output data transfer without threshold.

25.6.29 Synchronous output data transfer with threshold

For the operation process, please refer to the chapter Asynchronous output data transfer without threshold.

25.6.30 Synchronous output data transfer not completed

1. The interrupt flag bit USBFS_GINTSTS.incompISOIN is set to indicate that at least one synchronous output endpoint has an incomplete transfer in the current frame.
2. If the incomplete transfer of this endpoint is because the synchronous output data has not been completely cleared, the program must clear all synchronous output data in the receive FIFO.
3. When all the data in the receive FIFO is cleared, the program can detect the USBFS_DOEPINTn.XferCompl interrupt. In this case, the program must re-enable the endpoint to receive isochronous output data in the next frame.
4. When the interrupt flag USBFS_GINTSTS.incompISOIN is set, the program must read the control registers (USBFS_DOEPCTLn) of all synchronous output endpoints to determine which endpoint has an incomplete transfer in the current frame.
5. The previous steps must be completed before the USBFS_GINTSTS.SOF interrupt flag is set to ensure that the current frame number has not changed.
6. When an incomplete transfer occurs on a synchronous output endpoint, the program must discard the data in memory and disable the endpoint. USBFS_DOEPCTLn.EPDis = 1.
7. Wait for the interrupt flag bit USBFS_DOEPINTn.EPDisbl to be set, and then re-enable the endpoint to receive new data for the next frame.

25.6.31 Periodic input data transfer without threshold

1. XferSize and PktCnt fields of programming register USBFS_DIEPTSIzn, programming register USBFS_DIEPDMAn.
2. According to the endpoint characteristic programming register USBFS_DIEPCTLn, set the CNAK bit and the EPEna bit.
3. The USBFS_DIEPINTn.INTknTXFEmp interrupt flag is set to indicate that the DMA has not transferred all the data to the transmit FIFO.
4. If the interrupt endpoint is already enabled, ignore the interrupt in step 3. If the synchronous endpoint has already been enabled, the interrupt in step 3 occurs.
5. When the interrupt flag bit USBFS_DIEPINTn.XferCompl is set, but the USBFS_DIEPINTn.INTknTXFEmp interrupt flag bit is not set, it means that the synchronous input transfer is successfully completed. Read the XferSize and PktCnt fields of the register USBFS_DIEPTSIzn, and the values are both 0, indicating that all data has been transferred.
6. When the interrupt flag USBFS_DIEPINTn.XferCompl is set, and the USBFS_DIEPINTn.INTknTXFEmp interrupt flag is set or not set, it means that the interrupt input transmission is successfully completed. Read the XferSize and PktCnt fields of the register USBFS_DIEPTSIzn, and the values are both 0, indicating that all data has been transferred.

7. The interrupt flag USBFS_GINTSTS.incomplSOIN is set to indicate that the controller has not received at least one cycle input token packet in the current frame.

25.6.32 Periodic input data transfers have thresholds

1. XferSize and PktCnt fields of programming register USBFS_DIEPTSIzn, programming register USBFS_DIEPDMAAn.
2. According to the endpoint characteristic programming register USBFS_DIEPCTLn, set the CNAK bit and the EPEna bit. At the same time, specify the transmit FIFO number in the register USBFS_DIEPCTLn.TXFNum field.
3. The USBFS_DIEPINTn.INTknTXFEmp interrupt flag is set to indicate that the DMA has not transferred all the data to the transmit FIFO.
4. If the interrupt endpoint is already enabled, ignore the interrupt in step 3. If the synchronous endpoint has already been enabled, the interrupt in step 3 occurs.
5. When the interrupt flag bit USBFS_DIEPINTn.XferCompl is set, but the USBFS_DIEPINTn.INTknTXFEmp interrupt flag bit is not set, it means that the synchronous input transfer is successfully completed. Read the XferSize and PktCnt fields of the register USBFS_DIEPTSIzn, and the values are both 0, indicating that all data has been transferred.
6. When the interrupt flag USBFS_DIEPINTn.XferCompl is set, and the USBFS_DIEPINTn.INTknTXFEmp interrupt flag is set or not set, it means that the interrupt input transmission is successfully completed. Read the XferSize and PktCnt fields of the register USBFS_DIEPTSIzn, and the values are both 0, indicating that all data has been transferred.
7. The interrupt flag USBFS_GINTSTS.incomplSOIN is set to indicate that the controller has not received at least one cycle input token packet in the current frame.
8. The interrupt flag USBFS_DIEPINTn.TxFifoUndrn is set to indicate that the synchronous transmission of the current frame has a low flow rate. The program can choose to ignore this interrupt, because this interrupt is often caused by USBFS_GINTSTS.incomplSOIN at the end of the periodic frame.

25.7 Register description

The application program controls the USBFS module by reading and writing the control and status registers through the AHB slave interface. All registers of the USBFS module are 32-bit registers, and their addresses are aligned by 32 bits, so they can only be accessed in 32-bit mode.

The control and status registers are divided into the following categories:

- Module global registers
- Device Mode Register
- Power and Clock Gating Control Registers

For the list of USBFS module registers and the base address, please refer to Table 25-3 List of USBFS registers.

USBFS module register base address: 0x40040000

Table 25-3 List of USBFS registers

25.7.1 USBFS global registers

25.7.1.1 USBFS AHB Control Register (USBFS_GAHBCFG)

AHB Configuration Register

Offset address: 0x08

Reset value: 0x0000 0000

This register can be used to configure the module after power-up or when changing role modes.

This register mainly contains configuration parameters related to the AHB system.

b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Reserved															
b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Reserved								Reser ved	Reser ved	Reser ved	DMA EN	HBSTLEN[3:0]			GINT MSK

The application must program this register before starting any AHB or USB transaction. Do not change this register after initial programming.

Bit	Marking	Place name	Function	Read and write
b31~b9	Reserved	-	The reset value must be maintained.	R
b8	Reserved	-	The reset value must be maintained.	R
b7	Reserved	-	The reset value must be maintained.	R
b6	Reserved	-	The reset value must be maintained.	R
b5	DMAEN	DMA enable	DMA enable (DMA enable) 0: Module operates in slave mode 1: The module operates in DMA mode	R/W
b4~b1	HBSTLEN	Batch length/type	Batch length / type (Burst length/type) 0000b: single 0001b: INCR 0011:INCR4 0101:INCR8 0111:INCR16 Other values: reserved	R
b0	GINTMSK	Global Interrupt Mask	Global interrupt mask This bit is used to mask or unmask global interrupts. The Interrupt Status Register is updated by the module regardless of the setting of this bit. 0: Mask interrupts triggered by the application 1: Unmask application-triggered interrupts	R/W

25.7.1.2 USBFS USB Configuration Register (USBFS_GUSBCFG)

USBFS USB configuration register

Offset address: 0x00C

Reset value: 0x0000 0A00

This register configures the module. It contains configuration parameters related to USB and USB-PHY.

The application must program this register before starting any AHB or USB transaction. Do not change this register after initial programming.

b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Reserved															
Bit	Marking	Place name	Function										Read and write		
b31~b14	Reserved	-	The reset value must be maintained.										R		
b13~b10	TRDT	USB turnaround time	USB turnaround time Set the turnaround time in units of PHY clocks. To calculate the value of TRDT, use the following formula: $TRDT = 4 \times AHB\ clock + 1\ PHY\ clock$ For example: 1. If AHB clock frequency = 84 MHz (PHY clock frequency = 48 MHz), then TRDT is set to 9. 2. If AHB clock frequency = 48 MHz (PHY clock frequency = 48 MHz), then TRDT is set to 5.										R/W		
b9~b7	Reserved	-	The reset value must be maintained.										R		
b6	PHYSel	Full-Speed Family Transceiver Selection	Full Speed serial transceiver select This bit is write-only and is always 1.										W		
b5~b3	Reserved	-	The reset value must be maintained.										R		
b2~b0	TOCAL	FS timeout calibration	FS timeout calibration (FS timeout calibration) Additional latency introduced by the PHY includes the number of PHY clocks set by the application in this field, and the module's full-speed inter-packet timeout interval. The delay introduced by different PHYs has different effects on the state of the data line. The USB standard timeout value for full speed operation is 16 to 18 single digit times, inclusive. The application must program this field according to the enumerated speed. The number of bit times added per PHY clock is 0.25 bit times.												

25.7.1.3 USBFS Reset Register (USBFS_GRSTCTL)

USBFS reset register

Offset address: 0x10

Reset value: 0x8000 0000

The application program resets various hardware features in the module through this register.

b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16					
AHBI DL	DMA REQ	Reserved																		
b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0					
Reserved					TXFNUM[4:0]					TXFF LSH	RXFF LSH	Reser ved	Reser ved	HSRS T	CSRS T					
<hr/>																				
Bit	Marking	Place name	Function												Read and write					
b31	AHBIDL	AHB Master Idle	AHB master idle (AHB master idle) Indicates that the AHB master state machine is in an idle condition.												R					
b30	DMAREQ	AHB Master Idle	DMA request signal (DMA request signal) This bit indicates that a DMA request is in progress. Used for debugging.												R					
b29~b11	Reserved	-	Read as "0", write as "0"												R					
b10~b6	TXFNUM	TxFIFO number	TxFIFO number (TxFIFO number) FIFO number for FIFO flushing using the TxFIFO flush bit. This field should only be changed after the module has cleared the TxFIFO flush bit. <ul style="list-style-type: none">● 00000: Refresh Tx FIFO 0● 00001: Flush TXFIFO 1● 00010: refresh TXFIFO 2...● 00101: refresh TXFIFO 15● 10000: refresh all transmit FIFOs												R/W					
b5	TXFFLSH	TxFIFO refresh	TxFIFO refresh (TxFIFO flush) This bit selectively flushes one or all transmit FIFOs, but cannot do so while the module is processing a communication transaction. The application can only write to this bit after confirming that the module is not currently reading or writing to the TxFIFO. Confirm with the following registers: <ul style="list-style-type: none">— Read: NAK active interrupt ensures that the module is not currently performing a read operation on the FIFO— Write: The AHBIDL bit in USBFS_GRSTCTL ensures that the module is not currently doing any writes to the FIFO												R/W					
b4	RXFFLSH	RxFIFO refresh	RxFIFO refresh (RxFIFO flush) The application can use this bit to flush the entire RxFIFO, but must first ensure that the module is not currently processing a communication transaction. The application can write to this bit only after confirming that the module is not currently reading or writing to the RxFIFO. The application must wait until this bit is cleared before performing other operations. Usually there is a wait of 8 clock cycles (whichever is the slowest of the PHY or AHB clock).												R/W					
b3~b2	Reserved	-	The reset value must be maintained.												R					
b1	HSRST	HCLK domain logic soft reset	HCLK domain logic soft reset (HCLK soft reset) Applications use this bit to refresh the control logic in the AHB clock domain. Only the AHB clock domain pipeline is reset. FIFO is not flushed by this bit. After the transaction on the AHB is terminated according to the protocol, all state machines in the AHB clock domain are reset to the idle state. The CSR control bit used by the AHB clock domain state machine is cleared. To clear this interrupt, the status mask bit generated by the AHB clock domain state machine and used to control the status of the interrupt needs to be cleared. Since the interrupt status bit is not cleared, the application can get the status of all module events that occurred after this bit was set. state.												R/W					

<p>This bit is self-clearing and the module will clear it when all necessary logic in it is reset. This process requires several clocks of time, depending on the current state of the module.</p>			
b0	CSRST	Module soft reset	R/W

Module soft reset (Core soft reset)
 Reset the HCLK and PCLK domains as follows:
 Clear individual interrupt and all CSR register bits except:
 — RSTPDMODL bit in USBFS_PCGCCTL
 — GAYEHCLK bit in USBFS_PCGCCTL
 — PWRCOMP bit in USBFS_PCGCCTL
 — STPPCLK bit in USBFS_PCGCCTL
 — FSLSPCS bit in USBFS_HCFG
 — DSPD bit in USBFS_DCFG
 Resets all module state machines (except AHB slaves) to idle state and clears all transmit and receive FIFOs.
 Terminate all transactions on the AHB master as soon as possible after the final data phase of the AHB transfer. Immediately terminates all transactions on the USB.
 The application can write to this bit anytime it needs to reset the module. This bit is self-clearing and the module will clear it after all necessary logic in it is reset, which takes several clocks depending on the current state of the module. Once this bit is cleared, software must wait at least 3 PHY clocks before accessing the PHY domain (synchronous delay). In addition, the software must also be determined that bit 31 in this register is set (AHB Master Idle) before starting operation.
 Software reset is usually used in two situations, one is during software development, and the other is after the user dynamically changes the PHY selection bits in the USB configuration registers listed above. When the user changes the PHY, the corresponding clock will be selected for the PHY and used in the PHY domain. Once a new clock is selected, the PHY domain must be reset for proper operation.

25.7.1.4 USBFS Global Interrupt Status Register (USBFS_GINTSTS)

USBFS interrupt status register

Offset address: 0x14

Reset value: 0x14000020

This register is used to interrupt the application with system level events.

The FIFO status interrupts are read-only; if software reads or writes to the FIFO while these interrupts are being processed, the FIFO interrupt flag is automatically cleared.

Before enabling the interrupt bit, the application must clear the USBFS_GINTSTS register during initialization to avoid any interrupts before initialization.

b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Bit	Marking	Place name	Function	Read and write
b31	WKUPINT	Resume/Remote Wake Interrupt Detected	Resume / remote wakeup detected interrupt When a resume signal is detected on the USB bus, the interrupt will be triggered and cleared by writing 1 to this bit by software.	R/W
b30	VBU SINT	VBUS active interrupt	VBUSy valid interrupt (VBUS valid interrupt) In device mode, when the USBFS_VBUS pin is detected to change from low to high, the interrupt will be triggered. Write 1 to this bit to clear it to 0 by software.	R/W
b29~b23	Reserved	-	The reset value must be maintained.	R
b22	DATAFSUSP	Data fetch pending	Data fetch suspended This interrupt is only valid in DMA mode. This interrupt indicates that the module stopped fetching data for the IN endpoint due to unavailable Tx FIFO space or request queue space. The application uses this interrupt in the endpoint mismatch algorithm. For example, after detecting an endpoint mismatch, the application would do the following: — Set the global aperiodic IN NAK handshake signal to 1 — Disable IN endpoints — empty FIFO — Determine the token sequence based on the IN token sequence learning queue — re-enable the endpoint — If the global aperiodic IN NAK is cleared but the module has not yet acquired data for the IN endpoint and an IN token has been received at the same time, clear the global aperiodic IN NAK handshake signal: the module will generate "FIFO is empty when receiving IN token" interrupt. USBFS then sends a NAK response to the host. To avoid this situation, the application can check the DATAFSUSP interrupt in USBFS_GINTSTS, which can ensure that the global NAK handshake signal is cleared after the FIFO is full. Alternatively, the application can mask the "IN token received while FIFO empty interrupt" while clearing the global IN NAK handshake signal. Write 1 to this bit to clear it to 0 by software.	R/W
b21	INCOMPISOO UT	Incomplete OUT synchronous transfer	INCOMPISOOUT: Incomplete isochronous OUT transfer When the module asserts this interrupt, it indicates that there is an outstanding transfer on at least one isochronous OUT endpoint in the current frame. This interrupt is triggered with the Periodic End of Frame Interrupt (EOPF) bit in this register. Write 1 to this bit to clear it to 0 by software.	R/W
b20	IISOIXFR	IN SYNC TRANSFER NOT COMPLETED	Incomplete isochronous IN transfer When the module sets this interrupt to 1, it indicates that the	R/W

			transmission on at least one synchronous IN endpoint in the current frame is not completed. This interrupt is triggered with the Periodic End of Frame Interrupt (EOPF) bit in this register. Write 1 to this bit to clear it to 0 by software.	
b19	OEPINT	OUT endpoint interrupt	OUT endpoint interrupt (OUT endpoint interrupt) When the module sets this bit, it indicates that there is an interrupt pending on an OUT endpoint in the module (in device mode). The application must read the host USBFS_DAINT register to determine the exact number of the OUT endpoint on which the interrupt occurred, and then read the corresponding USBFS_DOEPINTx register to determine the exact cause of the interrupt. The application must clear the corresponding status bit of the corresponding USBFS_DOEPINTx register before clearing this bit.	R
b18	IEPINT	IN endpoint interrupt	IN endpoint interrupt (IN endpoint interrupt) When the module sets this bit, it indicates that there is an interrupt pending on an IN endpoint in the module (in device mode). The application must read the host USBFS_DAINT register to determine the exact number of the IN endpoint where the interrupt occurred, and then read the corresponding USBFS_DIEPINTx register to determine the exact cause of the interrupt. The application must first convert the corresponding The corresponding status bit of the USBFS_DIEPINTx register must be cleared before the bit can be cleared.	R
b17~b16	Reserved	-	The reset value must be maintained.	R
b15	EOPF	Periodic end-of-frame interrupt	End of periodic frame interrupt Indicates that the current frame has reached the period specified by the Periodic Frame Interval field (PFIVL bit in USBFS_DCFG) in the USBFS_DCFG register. Write 1 to this bit to clear it to 0 by software.	R/W
b14	ISOODRP	Drop sync OUT packet interrupt	Isochronous OUT packet dropped interrupt The module sets this bit to 1 if the module cannot write a sync OUT packet to the RxFIFO due to insufficient space in the RxFIFO to accommodate the largest packet for the sync OUT endpoint. Write 1 to this bit to clear it to 0 by software.	R/W
b13	ENUMDNE	Enum complete interrupt	Enumeration done interrupt When the module sets this bit to 1, it indicates that the velocity enumeration is complete. The application must read the USBFS_DSTS register to obtain the enumerated speed. Write 1 to this bit to clear it to 0 by software.	R/W
b12	USBRST	USB reset interrupt	USB reset interrupt When the module sets this bit, it indicates that a reset signal was detected on the USB. Write 1 to this bit to clear it to 0 by software.	R/W
b11	USBSUSP	USB suspend interrupt	USB suspend interrupt When the module sets this bit, it indicates that a suspend condition has been detected on the USB. When the idle state on the USB bus remains for 3ms, the module will enter the suspend state. Write 1 to this bit to clear it to 0 by software.	R/W
b10	ESUSP	Early hang interrupt	Early suspend interrupt When the module sets this bit to 1, it indicates that the USB has been detected to be idle for 3ms.	R/W
b9~b8	Reserved	-	The reset value must be maintained.	R
b7	GONAKEFF	Global OUT NAK active interrupt	Global OUT NAK effective interrupt (Global OUT NAK effective interrupt) Indicates that the "set global OUT NAK" bit (SGONAK bit in USBFS_DCTL) set by the application in the USBFS_DCTL register has taken effect in the module. This bit is cleared by writing to the "Clear Global OUT NAK" bit in the USBFS_DCTL register (CGONAK bit in USBFS_DCTL).	R
b6	GINAKEFF	Global aperiodic IN NAK active interrupt	Global IN nonperiodic NAK effective interrupt Indicates that the "Set Global Aperiodic IN NAK" bit (SGINAK bit in USBFS_DCTL) set by the application in the USBFS_DCTL register has taken effect in the module. That is, the module has sampled the global IN NAK bit set by the application, and the result has taken effect. This bit is cleared by clearing the Clear Global Aperiodic IN NAK bit in the USBFS_DCTL register (CGINAK bit in USBFS_DCTL). This interrupt does not necessarily indicate that a NAK handshake has been sent on the USB. The STALL bit has priority over the NAK bit.	R
b5	Reserved	-	The reset value must be maintained.	R
b4	RXFNE	RxFIFO not empty interrupt	RxFIFO non-empty interrupt (RxFIFO non-empty interrupt) Indicates that there is at least one packet in the RxFIFO waiting to be read.	R
b3	SOF	Start of frame interrupt	Start of frame interrupt When the module sets this bit, it indicates that a SOF token has been received on the USB. The application program can get the current frame number by reading the device status register. This interrupt occurs only when the module is running in FS mode.	R/W

Write 1 to this bit to clear it to 0 by software.

b2~b0

Reserved

-

The reset value must be maintained.

R

25.7.1.5 USBFS Global Interrupt Mask Register (USBFS_GINTMSK)

USBFS interrupt mask register

Offset address: 0x18

Reset value: 0x00000000

This register is used in conjunction with the module interrupt register to interrupt the application. If an interrupt bit is masked, the interrupt associated with that bit will not be generated.

However, the module interrupt (USBFS_GINTSTS) register bit corresponding to the interrupt will still be set.

25.7.1.6 USBFS receive status debug read /USBFS status read and stack register (USBFS_GRXSTSR/USBFS_GRXSTSP)

USBFS Receive status debug read/USBFS status read and pop registers

Read offset address: 0x01C

The offset address of the stack: 0x020

Reset value: 0x0000 0000

Reading the receive status debug read register will return the contents of the top of the receive FIFO. Reading the Receive Status Read and Pop registers will additionally pop the data entry from the top of the RxFIFO.

When the receive FIFO is empty, the module will ignore the read or stack operation of the register and return the value 0x0000 0000. The application must only pop the receive status FIFO when the Receive FIFO Not Empty bit of the Module Interrupt Register (RXFNE bit in USBFS_GINTSTS) is set.

Bit	Marking	Place name	Function												Read and write			
b31~b12	Reserved	-	The reset value must be maintained.												R			
b11	POPRGDNE	Power-on programming complete	Power-on programming done The application uses this bit to indicate that the register has finished programming after waking up from power-down mode.												R/W			
b10	CGONAK	Clear global OUT NAK	Clear global OUT NA (Clear global OUT NAK) Writing to this bit will clear the global OUT NAK.												W			
b9	SGONAK	Set global OUT NAK	Set global OUT NAK (Set global OUT NAK) Writing to this bit sets the global OUT NAK. Applications use this bit to send NAK handshake signals on all OUT endpoints. The application program can only set this bit to 1 when it is sure that the global OUT NAK valid bit (GONAKEFF bit in USBFS_GINTSTS) in the module interrupt register has been cleared.												W			
b8	CGINAK	Clear global IN NAK	Clear global IN NAK (Clear global IN NAK) Writing to this bit will clear the global IN NAK.												W			
b7	SGINAK	Set global IN NAK	Set global IN NAK (Set global IN NAK) Writing to this field sets the global aperiodic IN NAK. Applications use this bit to cause all aperiodic IN endpoints to send NAK handshake signals. The application program can only set this bit to 1 when it is sure that the global IN NAK valid bit (GINAKEFF bit in USBFS_GINTSTS) in the module interrupt register has been cleared.												W			
b6~b4	Reserved	-	The reset value must be maintained.												R			
b3	GONSTS	Global OUT NAK status	Global OUT NAK status (Global OUT NAK status) 0: Handshake will be sent according to FIFO status and NAK and STALL bit settings. 1: No data is received regardless of whether there is free space in the Rx FIFO. Reply NAK handshake to all received packets except SETUP transactions. All OUT packets of type isochronous will be dropped.												R			
b2	GINSTS	Global IN NAK status	Global IN NAK status (Global IN NAK status) 0: Handshake will be replied based on data availability in transmit FIFO. 1: Make all aperiodic IN endpoints reply with NAK handshake signals, regardless of the availability of data in the send FIFO.												R			
b1	SDIS	soft disconnect	Soft disconnect The application uses this bit to signal the USBFS module to perform a soft disconnect. When this bit is set, the host will not see that the device is attached, and the device will not receive signals on the USB. The module remains disconnected until the application program clears this bit. 0: Normal operation. Clearing this bit after a soft disconnect causes the host to receive a device connected event. After reconnecting the device, the USB host restarts device enumeration. 1: Make the host receive a device disconnect event.												R/W			
b0	RWUSIG	Send a remote wakeup signal	At full speed, the minimum time for soft disconnection is specified as follows: Suspended state: the minimum time is 1ms+2.5us Idle state: 2.5us Non-idle or suspend state: 2.5us												R/W			

ms of setting it.

25.7.2.3 USBFS Device Status Register (USBFS_DSTS)

USBFS Device status register

Offset address: 0x808

Reset value: 0x0000 0002

This register indicates the state of the module when a USB related event occurs. When an interrupt occurs, the interrupted endpoint information must be read from the device overall interrupt (USBFS_DAINT) register.

b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Reserved										FNSOF[13:8]

<hr/>															
Bit	Marking	Place name	Function	Read and write											
b31~b22	Reserved	-	The reset value must be maintained.	R											
b21~b8	FNSOF	Frame number of received SOF	Frame number of the received SOF (Frame number of the received SOF)	R											
b7~b4	Reserved	-	The reset value must be maintained.	R											
b3	EERR	Indeterminate error	Erratic error The module sets this bit to report any pending errors. Due to an indeterminate error, the USBFS controller enters the suspend state and generates an interrupt to the early suspend bit of the USBFS_GINTSTS register (ESUSP bit in USBFS_GINTSTS). If the early hang interrupt was triggered by an indeterminate error, the application can only perform a soft disconnect to resume communication.	R											
b2~b1	ENUMSPD	Enumeration speed	Enumerated speed Indicates the speed that the USBFS controller is enumerated after detecting the speed through the chirp sequence. 01: reserved 10: reserved 11: Full speed (PHY clock running at 48 MHz) Other values: reserved	R											
b0	SUSPSTS	Suspended state	Suspend status In device mode, this bit is set whenever a suspend condition is detected on the USB. When the idle state on the USB bus is kept for 3ms, the module will enter the suspend state. A module exits the suspended state when: — Activity on the USB cable — The application writes to the remote wakeup signal bit of the USBFS_DCTL register (RWUSIG bit in USBFS_DCTL).	R											

25.7.2.4 USBFS Device IN Endpoint General Interrupt Mask Register (USBFS_DIEPMSK)

USBFS Device IN endpoint common interrupt mask register

Offset address: 0x810

Reset value: 0x0000 0000

This register works in conjunction with the individual USBFS_DIEPINTx registers for all endpoints to generate interrupts on each IN endpoint. IN endpoint interrupts in the USBFS_DIEPINTx registers can be masked by writing to the corresponding bit in this register. By default, status interrupts are masked.

b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

25.7.2.6 USBFS Device Global Endpoint Interrupt Register (USBFS_DAINT)

USBFS Device OUT endpoint common interrupt mask register

Offset address: 0x818

Reset value: 0x0000 0000

When a valid event occurs on the endpoint, the USBFS_DAINT register will interrupt the application via the device OUT endpoint interrupt bit or the device IN endpoint interrupt bit in the USBFS_GINTSTS register (OEPINT or IEPINT bits in USBFS_GINTSTS, respectively). Each endpoint corresponds to an interrupt bit, and both the OUT endpoint and the IN endpoint have up to 16 interrupt bits. Bidirectional endpoints will use the corresponding IN and OUT interrupt bits. When the application sets and clears a bit in the corresponding Device Endpoint x Interrupt Register (USBFS_DIEPINTx/USBFS_DOEPINTx), the corresponding bit in this register is also set and cleared.

USBA EP															MPSIZ[1:0]

This register is used to control Control Transfer Endpoint 0.

Bit	Marking	Place name	Function	Read and write
b31	EPENA	Endpoint enable	Endpoint enable The application sets this bit to start a data send on endpoint 0. The module clears this bit before any of the following interrupts are triggered on this endpoint: — Endpoint prohibition — Transmission completion	R/W
b30	EPDIS	Endpoint prohibition	Endpoint disable An application can set this bit to stop sending data on an endpoint even before the transfer on that endpoint is complete. The application must wait for an endpoint disable interrupt to occur before the endpoint is considered disabled. The module will clear this bit before the endpoint disable interrupt bit is set. An application can set this bit only if the Endpoint Enable bit for that endpoint is set.	R/W
b29~b28	Reserved	-	The reset value must be maintained.	R
b27	SNAK	Set the NAK bit	Set the NAK bit (Set NAK) Writing to this bit will set the NAK bit of the endpoint. With this bit, the application can control the sending of NAK handshake signals on the endpoint. The module can also set this bit of the endpoint to 1 after the endpoint receives the SETUP packet.	R/W
b26	CNAK	Clear the NAK bit	Clear the NAK bit (Clear NAK) Writing to this bit will clear the NAK bit of the endpoint.	R/W
b25~b22	TXFNUM	TxFIFO number	TxFIFO number (TxFIFO number) This value is set to the FIFO number assigned to IN endpoint 0.	R/W
b21	STALL	STALL handshake	STALL handshake (STALL handshake) The application can only set this bit to 1, the module will clear this bit to 0 when the endpoint receives a SETUP token. If the NAK bit, global IN NAK, or global OUT NAK and this bit are both set, the STALL bit takes precedence.	R/W
b20	Reserved	-	The reset value must be maintained.	R
b19~b18	EPTYP	Endpoint type	Endpoint type The hardware is set to '00', indicating a control type endpoint.	R
b17	NAKSTS	NAK state	NAK status Indicates the following results: 0: Module replies to non-NAK handshake according to FIFO status. 1: The module replies with a NAK handshake on this endpoint. When this bit is set (either by the application or by the module), the module stops sending data even if there is still data available in the TxFIFO. Regardless of how this bit is set, the module always responds to SETUP packets with an ACK handshake.	R
b16	Reserved	-	The reset value must be maintained.	R
b15	USBAEP	USB active endpoint	USB active endpoint This bit is always set to 1, indicating that Control Endpoint 0 is always active in all configurations and interfaces.	R
b14~b2	Reserved	-	The reset value must be maintained.	R
b1~b0	MPSIZ	Maximum Packet Size	Maximum packet size Applications must program this field to the maximum packet size for the current logical endpoint. 00: 64 bytes 01: 32 bytes	R/W

10: 16 bytes
11: 8 bytes

25.7.2.13 USBFS device IN endpoint x control register (USBFS_DIEPCTLx) (x=1..4)

USBFS Device IN endpoint x control register

Offset address: 0x900 + (endpoint number × 0x20)

Reset value: 0x0000 0080

Applications use this register to control the behavior of individual logical endpoints (except Endpoint 0).

b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
USBA EP		Reserved										MPSIZ[10:0]			

Bit	Marking	Place name	Function	Read and write
b31	EPENA	Endpoint enable	Endpoint enable The application sets this bit to initiate data sending on the endpoint. The module clears this bit before any of the following interrupts are triggered on this endpoint: — SETUP phase completed — Endpoint prohibition — Transmission completion	R/W
b30	EPDIS	Endpoint prohibition	Endpoint disable An application can set this bit to stop sending data on an endpoint even before the transfer on that endpoint is complete. The application must wait for an endpoint disable interrupt to occur before the endpoint is considered disabled. The module will clear this bit before the endpoint disable interrupt bit is set. An application can set this bit only if the Endpoint Enable bit for that endpoint is set.	R/W
b29	SODDFRM	set odd-numbered frames	odd frame Applies only to synchronous IN and OUT endpoints. Writing to this field sets the Even/odd-numbered frame (EONUM) field to odd-numbered frames.	R/W
b28	SD0PID/ SEVNFRM	set DATA0 PID/ SEVNFRM	Set DATA0 PID (Set DATA0 PID) Applies to interrupt/bulk IN endpoints only. Writing to this field sets the endpoint data PID (DPID) field in this register to DATA0. SEVNFRM: Set even frame (Set even frame) Applies only to synchronous IN endpoints. Writing to this field sets the Even/odd-numbered frames (EONUM) field to even frames.	R/W
b27	SNAK	Set the NAK bit	Set the NAK bit (Set NAK) Writing to this bit will set the NAK bit of the endpoint. With this bit, the application can control the sending of NAK handshake signals on the endpoint. When a transfer complete interrupt occurs on an endpoint After receiving SETUP, the module can also set this bit of the OUT endpoint to 1	R/W
b26	CNAK	Clear the NAK bit	Clear the NAK bit (Clear NAK) Writing to this bit will clear the NAK bit of the endpoint.	R/W
b25~b22	TXFNUM	TxFIFO number	TxFIFO number (Tx FIFO number) These bits are used to specify the FIFO number associated with this endpoint. A separate FIFO number must be set for each valid IN endpoint. This field is only valid for IN endpoints.	R/W
b21	STALL	STALL handshake	STALL handshake (STALL handshake) Setting this bit by the application causes the device to reply STALL to all tokens from the USB host. If the NAK bit, global IN NAK, or global OUT NAK is set at the same time as this bit, the STALL bit takes precedence. Only the application can clear this bit, not the module.	R/W
b20	Reserved	-	The reset value must be maintained.	R

		Endpoint type	Endpoint type The following are the transport types supported by this logical endpoint. 00: control 01: synchronous 10: Batch 11: interrupt	R
b19~b18	EPTYP	NAK state	NAK status – Indicates the following results: 0: Module replies to non-NAK handshake according to FIFO status. 1: The module replies with a NAK handshake on this endpoint. When an application or module sets this bit: For non-synchronous IN endpoints: The module stops sending any data through the IN endpoint even if there is data available in the TxFIFO. For synchronous IN endpoints: The module sends zero-length packets even if there is data available in the TxFIFO. Regardless of how this bit is set, the module always responds to SETUP packets with an ACK handshake.	R
b17	NAKSTS	Even/odd-numbered frames/Endpoint data PID	Even / odd frame Applies only to synchronous IN endpoints. Indicates the number of the frame in which the module sends/receives synchronized data for this endpoint. The application must program the even/odd-numbered frame number through the SEVNFRM and SODDFRM fields in this register for this endpoint to send/receive isochronous data. 0: even frame 1: odd-numbered frames DPID: Endpoint data PID (Endpoint data PID) Applies to interrupt/bulk IN endpoints only. Contains the PID of packets that will be received or sent on this endpoint. After an endpoint is activated, the application must program the PID of the first packet to be received or sent on this endpoint. The application programs the DATA0 or DATA1 PID using the SD0PID register field. 0: DATA0 1: DATA1	R/W
b16	EONUM/DPID	USB active endpoint	USB active endpoint Indicates whether this endpoint is active in the current configuration and interface. The module clears this bit to 0 for all endpoints except endpoint 0 when a USB reset is detected. After receiving the SetConfiguration and SetInterface commands, the application must program the endpoint register accordingly and set this bit to 1.	R/W
b14~b11	Reserved	-	The reset value must be maintained.	R/W
b10~b0	MPSIZ	Maximum Packet Size	Maximum packet size Applications must program this field to the maximum packet size for the current logical endpoint. This value is in bytes.	

25.7.2.14 USBFS device IN endpoint x interrupt register (USBFS_DIEPINTx) (x=0..4)

USBFS Device IN endpoint x interrupt register

Offset address: 0x908 + (endpoint number × 0x20)

Reset value: 0x0000 0000

This register indicates the status of the endpoint on USB and AHB related events. The application must read this register when the IN endpoint interrupt bit (IEPINT bit in USBFS_GINTSTS) is set in the module interrupt register. Before an application can read this register, it must first read the Device Entire Endpoint Interrupt (USBFS_DAINT) register to obtain the exact endpoint number of the device endpoint x interrupt register. The application must clear the corresponding bits in this register to clear the corresponding bits in the USBFS_DAINT and USBFS_GINTSTS registers.

b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Reserved															
b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Reserved															
Read and write															
Bit	Marking	Place name	Function												
b31~b8	Reserved	-	The reset value must be maintained.												
b7	TXFE	Transmit FIFO is empty	Transmit FIFO is empty (Transmit FIFO empty) This interrupt is asserted when the TxFIFO for this endpoint is half or fully empty. Whether the TxFIFO is half empty or fully empty is determined by the TxFIFO blank bit in the USBFS_GAHBCFG register (TXFELVL bit in USBFS_GAHBCFG).												
b6	INEPNE	IN endpoint NAK valid	INEPNE: IN endpoint NAK effective (IN endpoint NAK effective) This bit can be cleared when the application NAKs the IN endpoint by writing data to the CNAK bit in USBFS_DIEPCTLx. This interrupt indicates that the module has sampled a NAK that was set (by the application or the module), and the result has taken effect. This interrupt indicates that the IN endpoint NAK bit set by the application program has acted in the module. This interrupt does not guarantee that a NAK handshake was sent on the USB. The STALL bit has priority over the NAK bit. Software can also write 1 to clear this bit.												
b5	Reserved	-	The reset value must be maintained.												
b4	ITTXFE	IN token received when TxFIFO is empty	IN token received when TxFIFO is empty (IN token received when TxFIFO is empty) Applies to acyclic IN endpoints only. When the TxFIFO (periodic/aperiodic) corresponding to this endpoint is empty, an IN token is received and an interrupt is generated. Write 1 to clear by software.												
b3	TO	Time-out	Timeout condition Applies to control IN endpoints only. Indicates that this endpoint timed out on the most recently received IN token response. Write 1 to clear by software.												
b2	Reserved	-	The reset value must be maintained.												
b1	EPDISD	Endpoint disable interrupt	Endpoint disable interrupt This bit indicates that the endpoint has been disabled by the application. Write 1 to clear by software.												
b0	XFRC	Transfer complete interrupt	Transfer completed interrupt This field indicates that transfers set on this endpoint have completed transfers on USB and AHB. Write 1 to clear by software.												

25.7.2.15 USBFS device IN endpoint 0 transfer size register (USBFS_DIEPTSIZ0)

USBFS Device IN endpoint 0 transfer size register

Offset address: 0x910

Reset value: 0x0000 0000

The application must modify this register before enabling Endpoint 0. After enabling endpoint 0 through the endpoint enable bit (EPENA in USBFS_DIEPCTL0) in the device control endpoint 0 control register, the module modifies this register. The application can read this register only after the module has cleared the endpoint enable bit.

Non-zero endpoints use the registers of endpoints 1~5.

<hr/>															
Bit	Marking	Place name	Function	Read and write											
b31~b21	Reserved	-	The reset value must be maintained.	R											
b20~b19	PKTCNT	Packet count	Packet count Indicates the number of data packets included in one data transmission of endpoint 0. This field will be decremented each time a packet (max size or short) is read from the TxFIFO.	R/W											
b18~b7	Reserved	-	The reset value must be maintained.	R											
b6~b0	XFRSIZ	transfer size	Transfer size Indicates the amount of data contained in one data transmission of endpoint 0, in bytes. The module interrupts the application only after the application has transferred this data. The transfer size can be set to the endpoint's maximum packet size to break at the end of each packet. The module decrements this field each time a packet from external memory is written to the TxFIFO.	R/W											

25.7.2.16 USBFS device IN endpoint x transfer size register (USBFS_DIEPTSIZx) (x=1..4)

USBFS Device IN endpoint x transfer size register

Offset address: 0x910 + (endpoint number × 0x20)

Reset value: 0x0000 0000

The application must modify this register before enabling the endpoint. After enabling the endpoint through the endpoint enable bit (EPENA bit in USBFS_DIEPCTLx) in the USBFS_DIEPCTLx register, the module modifies this register. The application can read this register only after the module has cleared the endpoint enable bit.

XFRSIZ[15:0]																			

Bit	Marking	Place name	Function	Read and write
b31~b29	Reserved	-	The reset value must be maintained.	R
b28~b19	PKTCNT	Packet count	Packet count Indicates the number of data packets contained in a data transmission on this endpoint. This field will be decremented each time a packet (max size or short) is read from the TxFIFO.	R/W
b18~b0	XFRSIZ	transfer size	Transfer size This field contains the amount of data contained in a data transmission of the current endpoint, in bytes. The module interrupts the application only after the application has transferred this data. The transfer size can be set to the endpoint's maximum packet size to break at the end of each packet. The module decrements this field each time a packet from external memory is written to the TxFIFO.	R/W

25.7.2.17 USBFS device IN endpoint x DMA address register (USBFS_DIEPDMAx) (x=0..4)

USBFS Device IN endpoint x transfer size register

Offset address: 0x914 + (endpoint number × 0x20)

Reset value: 0x0000 0000

This register is used to set the DMA address in device endpoint DMA mode.

b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

25.7.2.21 USBFS device OUT endpoint x interrupt register (USBFS_DOEPINTx) (x=0..4)

USBFS Device OUT endpoint x interrupt register

Offset address: 0xb08 + (endpoint number × 0x20)

Reset value: 0x0000 0080

This register indicates the status of the endpoint on USB and AHB related events. The application must read this register when the OUT endpoint interrupt bit (OEPINT bit in USBFS_GINTSTS) in the USBFS_GINTSTS register is set. Before the application can read this register, it must first read the USBFS_DAINT register to get the exact endpoint number of the USBFS_DOEPINTx registers. The application must clear the corresponding bits in this register before clearing the corresponding bits in the USBFS_DAINT and USBFS_GINTSTS registers.

Bit	Marking	Place name	Function												
b31~b7	Reserved	-	The reset value must be maintained.												
b6	B2BSTUP	Received consecutive SETUP packets	Received consecutive SETUP packets (Back-to-back SETUP packets received) Applies to control OUT endpoints only. This bit indicates that this endpoint has received more than three consecutive SETUP packets. Software can also write 1 to clear this bit.												
b5	Reserved	-	The reset value must be maintained.												
b4	OTEPDIS	An OUT token was received when the endpoint prohibited	OUT token received when endpoint disabled Applies to control OUT endpoints only. Indicates that an OUT token was received when the endpoint was not yet enabled, generating an interrupt. Write 1 to clear by software.												
b3	STUP	SETUP stage completed	SETUP phase done (SETUP phase done) Applies to control OUT endpoints only. Indicates that the SETUP phase of the control endpoint is complete, and no consecutive SETUP packets are received in the current control transfer. On this interrupt, the application can decode the received SETUP packet. Write 1 to clear by software.												
b2	Reserved	-	The reset value must be maintained.												
b1	EPDISD	Endpoint disable interrupt	Endpoint disable interrupt This bit indicates that the endpoint has been disabled by the application. Write 1 to clear by software.												
b0	XFRC	Transfer complete interrupt	Transfer completed interrupt This field indicates that transfers set on this endpoint have completed transfers on USB and AHB. Write 1 to clear by software.												

25.7.2.22 USBFS device OUT endpoint 0 transfer size register (USBFS_DOEPTSIZ0)

USBFS Device OUT endpoint 0 transfer size register

Offset address: 0xB10

Reset value: 0x0000 0000

The application must modify this register before enabling Endpoint 0. After enabling endpoint 0 through the endpoint enable bit (EPENA in USBFS_DIEPCTL0) in the device control endpoint 0 control register, the module modifies this register. The application can read this register only after the module has cleared the endpoint enable bit.

Non-zero endpoints use the registers of endpoints 1~4.

b1	GATEHCLK	Gated HCLK	Gate HCLK (Gate HCLK) When the USB communication is suspended or the session is invalid, the application program will set this bit to stop clocking the modules except the AHB bus slave interface, master interface and wake-up logic. The application clears this bit when USB communication resumes or a new session starts.										R/W		
b0	STPPCLK	stop phy clock	Stop PHY clock (Stop PHY clock) The application sets this bit to stop the PH clock when USB communication is suspended, the session is invalidated, or the device is disconnected. The application program clears this bit when USB communication resumes.										R/W		

26 Controller Area Network (CAN)

26.1 Introduction

CAN (Controller Area Network) bus is a bus standard that can realize mutual communication between microprocessors or devices without a host. This module follows the CAN bus protocol 2.0A and 2.0B and is upwardly compatible with CAN-FD. The CAN bus controller can handle the data sending and receiving on the bus. In this product, CAN has 8 groups of filters. Filters are used to select messages for an application to receive.

The application sends data to the bus through a high-priority primary transmit buffer (Primary Transmit Buffer, hereinafter referred to as PTB) and 4 secondary transmit buffers (Secondary Transmit Buffer, hereinafter referred to as STB), which is determined by the transmit scheduler Email sending order. The bus data is obtained through 10 receive buffers (Receive Buffer, hereinafter referred to as RB). 4 STBs and 10 RBs can be understood as a 4-level FIFO and a 10-level FIFO, and the FIFO is completely controlled by hardware.

The CAN bus controller can also support time-triggered CAN communication (Time-trigger communication).

Main Features of CAN:

- Fully support CAN2.0A/CAN2.0B protocol.
- Upwardly compatible with CAN-FD protocol.
- Support the highest communication baud rate 1Mbit/s
- Support 1~1/256 baud rate prescaler, flexible configuration of baud rate.
- 10 receive buffers
 - FIFO mode
 - Errors or unreceived data will not overwrite stored messages
- 1 high priority main transmit buffer PTB
- 4 secondary transmit buffers STB
 - FIFO mode
 - priority arbitration
- 8 sets of independent filters
 - Support 11-bit standard ID and 29-bit extended ID
 - Programmable ID CODE bits and MASK bits
- PTB/STB support single sending mode
- Support silent mode
- Support loopback mode
- Supports capturing transmission error types and locating arbitration failure locations
- Programmable error warning value

- Support ISO11898-4 specified time trigger CAN and receive timestamp

26.2 CAN System Block Diagram

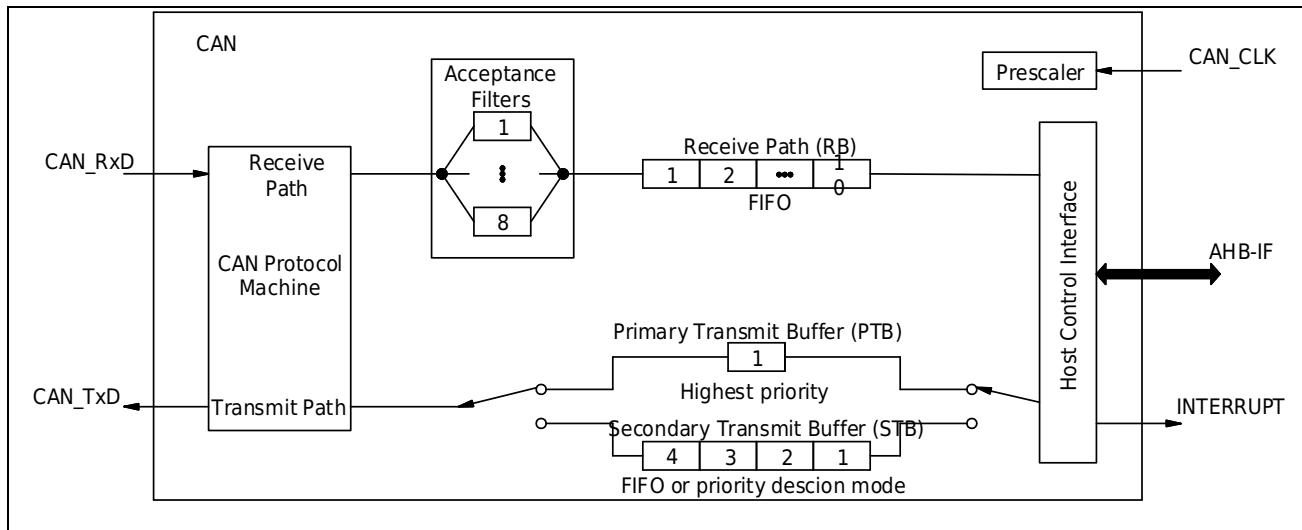

Figure 26-1 CAN System Block Diagram

26.3 Pin description

Table 26-1 CAN Pin Descriptions

Pin name	Direction	Functional description
CAN_RxD	Input	CAN receive data signal
CAN_TxD	Output	CAN sends data signal

26.4 Functional description

This chapter will describe the CAN function in detail.

26.4.1 Baud rate setting

The clock source of can_clk for CAN communication is an external high-speed oscillator. Before using CAN module, the CAN communication clock needs to be set in CMU chapter.

The figure below shows the CAN bit time definition diagram. The part on the dotted line is the bit time specified by the CAN protocol, and the part below the dotted line is the bit time defined by the CAN controller CAN-CTRL. Among them, segment1 and segment2 can be set through the register BT. The BT register can only be set when CFG_STAT.RESET=1, that is, when the CAN software is reset.

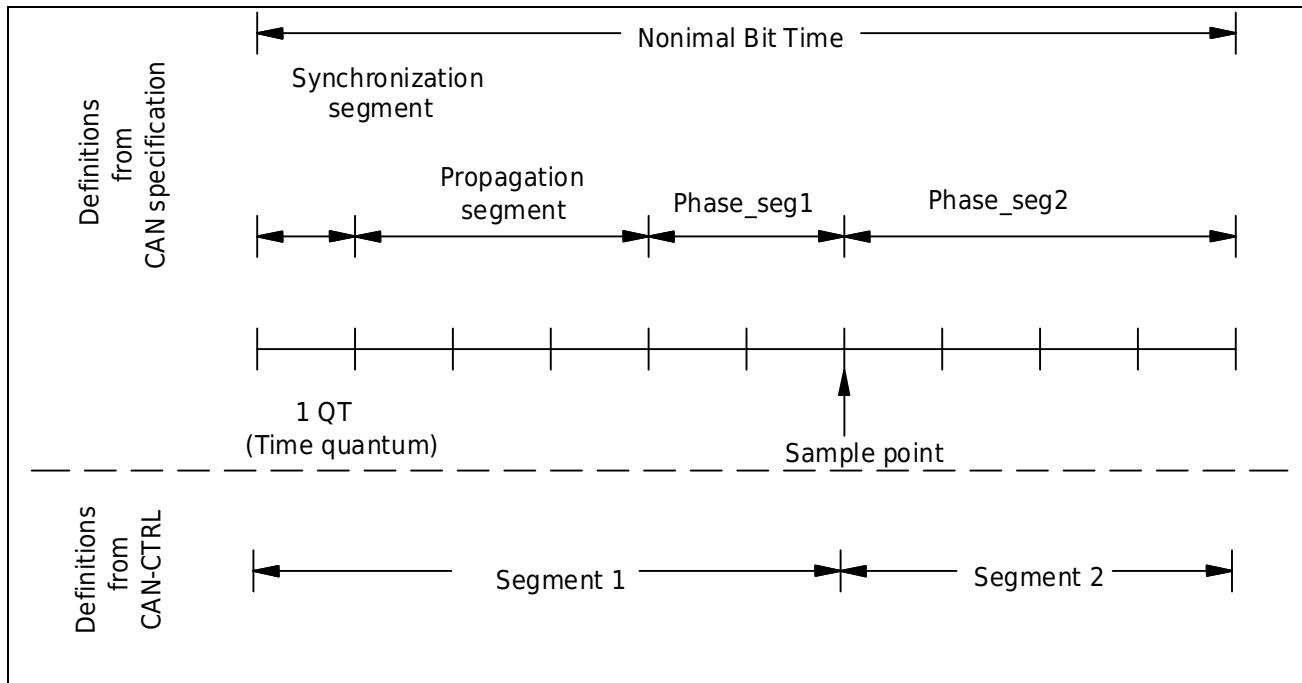

Figure 26-2 CAN bit time definition diagram

Please refer to the following formula for the TQ calculation method, where PRESC is set by the PRESC bit of the BT register . f_{can_clk} It is CAN communication clock frequency.

$$TQ = \frac{PRESC+1}{f_{can_clk}}$$

For the calculation method of sampling points, please refer to the following instructions:

- 1) If the PRESC bit of the BT register is set to ≥ 1 , refer to the sample point shown in Figure 30-2, the sampling point is located at the dividing point between segment1 and segment2;
- 2) If the PRESC bit of the BT register is set to 0, the sampling point is at the sample point, that is, 2 TQ positions in front of the segment1 and segment2 boundary points.

It is recommended to set the PRESC bit of the BT register to a value ≥ 1 .

Please refer to the following formula for the bit time calculation method, where SEG_1 and SEG_2 are set by the SEG_1 and SEG_2 bits of the BT register.

$$BT = t_{SEG1} + t_{SEG2} = ((SEG_1+2) + (SEG_2+1)) \times TQ$$

Table 26-2 CAN bit time setting rules

Bit	Predetermined area	Rule
SEG_1 bit of BT register	0~63	SEG_1 \geq SEG_2 + 1 SEG_2 \geq SJW
SEG_2 bit of BT register	0~7	
SJW bit of BT register	0~7	

26.4.2 Send buffer

CAN_CTRL provides two sending buffers for sending data, the main sending data buffer PTB and the secondary sending buffer STB. PTB has the highest priority, but only one frame of data can be buffered. STB has a lower priority than PTB, but it can buffer 4 frames of data, and 4 frames of data in STB can work in FIFO mode or priority arbitration mode.

The 4 frames in the STB say that the data can be sent by setting the TSALL bit of the TCMD register to 1. In the FIFO mode, the first written data is sent first. In the priority mode, the data with a small ID is sent first.

Data in a PTB has the highest priority, so a PTB send can postpone an STB send, but an STB that has already won arbitration and started sending cannot be delayed by a PTB send.

A frame of data in PTB and STB takes 4 words and can be accessed through the TBUF register. Select PTB or STB through the TBSEL bit of the TCMD register, TBSEL=0, select PTB, TBSEL=1, select STB. The next SLOT in the STB is selected by the TSNEXT bit of the TCTRL register. The corresponding relationship is shown in the figure below:

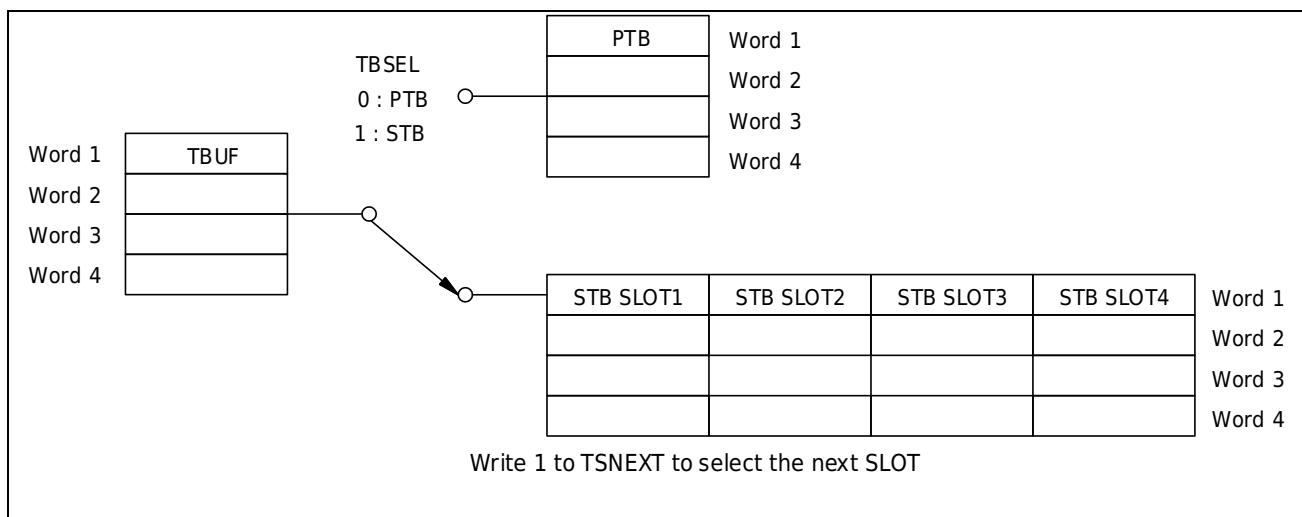

Figure 26-3 CAN TBUF register write transmit buffer and schematic diagram

26.4.3 Receive buffer

CAN_CTRL provides 10 SLOT receiving buffers for storing received data, and the 10 SLOT receiving buffers work in FIFO mode. Each RB SLOT needs to occupy 4 words, read the received data through the RBUF register, always read the earliest received data first, and set the RREL of the RCTRL register to 1 to release the read RB SLOT, and Points to the next RB SLOT.

The schematic diagram of reading RB SLOT through RBUF is as follows.

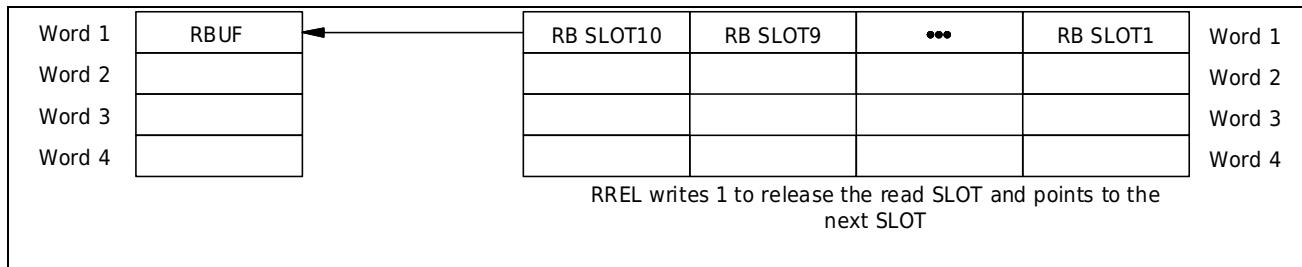

Figure 26-4 Schematic diagram of CAN RBUF register read receive buffer

26.4.4 Receive Filter Register Set

CAN_CTRL provides 8 sets of 32-bit filters to filter the received data to reduce CPU load. The filters can support standard format 11-bit ID or extended format 29-bit ID. Each set of filters has a 32-bit ID CODE register and a 32-bit ID MASK register. The ID CODE register is used to compare the received CAN ID, and the ID MASK register is used to select the CAN ID bit for comparison. When the corresponding ID MASK bit is 1, the ID CODE of this bit is not compared.

The received data will be received as long as it passes any of the 8 sets of filters, and the received data will be stored in RB, otherwise the data will not be received or stored.

Each group of filters is enabled or disabled through the ACFEN register. ID CODE and ID MASK are set by the SELMASK bit of the ACFCTRL register. When SELMASK=0, it points to ID CODE, and when SELMASK=1, it points to ID MASK. The filter is selected by the ACFADR bit of the ACFCTRL register. ID CODE and ID MASK are accessed through the ACF register and can only be set when CFG_STAT.RESET=1, that is, CAN software reset. Please refer to the figure below for the method of ACF registering and accessing the filter register group.

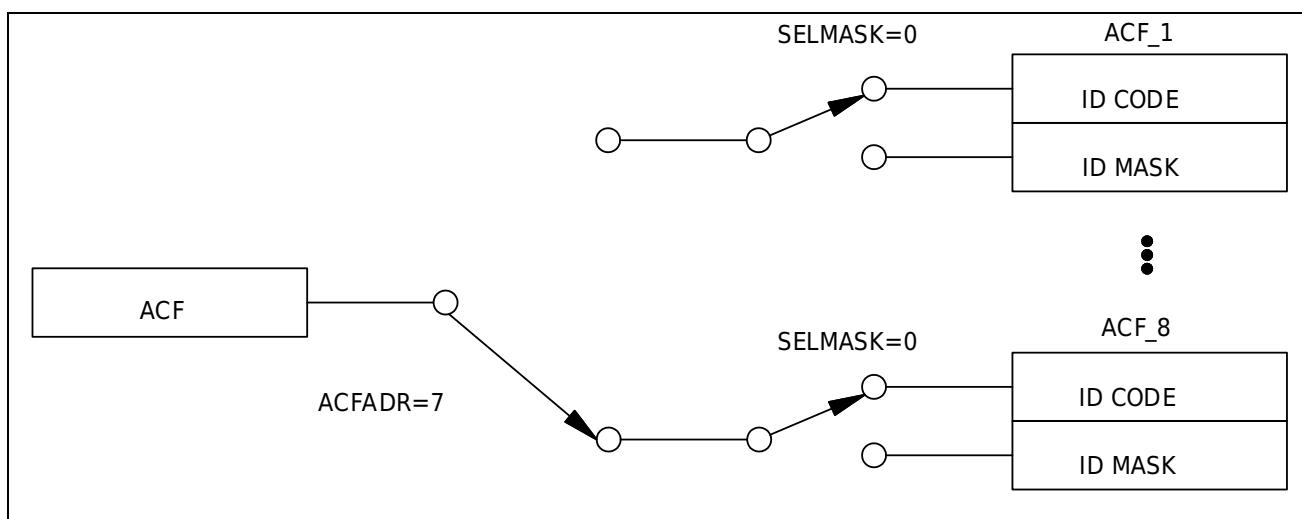

Figure 26-5 Schematic diagram of CAN ACF register access filter group

26.4.5 Data transmission

Before starting to send, it must be ensured that at least one frame of data in PTB or STB has been loaded. During PTB sending, TPE is locked, and the filling status of STB can be confirmed by TSSTAT bit. The sending data setting steps are as follows:

1. Set TBSEL to select sending BUF from PTB and STB
2. Write the data to be sent through the TBUF register.
3. STB is selected, set TSNEXT=1 to complete the loading of STB SLOT.
4. Send enable
 - PTB sent using TPE
 - STB sends using TSALL or TSONE
5. send complete status acknowledgment
 - PTB transmission is completed using TPIF, TPIE is used to enable TPIF
 - STB uses TSONE to send TSIF when it is completed, and TSIE is used to enable TSIF
 - STB uses TSIF when TSALL transmission is completed. At this time, after all the STB SLOT data that needs to be set are sent, TSIF is set, and TSIE is used to enable TSIF

26.4.6 Single data transmission

When the automatic resend function is not required, it can be set to single-send mode through the register. The TPSS bit of the CFG_STAT register is used for the single-send mode setting of PTB, and the TSSS bit is used for the single-send mode of STB. When the data is successfully sent, the action of single sending and normal sending mode is the same. But when the data is not sent successfully, the following results will appear:

- When TPIF is set (TPIE=1), the corresponding BUF SLOT data will be cleared.
- When an error is sent, KOER is updated and BEIF is set (BEIE=1).
- Arbitration fails, ALIF is set (ALIE=1).

In the single sending mode, TPIF cannot be used alone to judge whether the sending is completed. It needs to judge whether the sending is completed together with BEIF and ALIF.

26.4.7 Cancel data sending

Data transmissions that have been requested but not yet executed can be canceled via TPA or TSA. Cancellation of data transmission will occur in the following situations:

- in arbitration
 - If the node arbitration fails, the data transmission is canceled.
 - If the node arbitration is successful, it will continue to send.
- data sending
 - If data is successfully sent and ACK is received, the corresponding flag and status are normally set. Data transmission is not canceled.

- If the data is sent successfully but no ACK is received, the data sending is canceled and the error counter is incremented.
- The sending data set by TSALL=1, the STB SLOT data that is being sent are sent normally, and the STB SLOT that has not started sending is canceled.

The result of canceling data sending has the following two situations.

- TPA releases PTB and makes TPE=0.
- The TSA releases one STB SLOT or all STB SLOTS depending on whether TSONE or TSALL enabled transmission.

26.4.8 Data reception

The receive filter group can filter out unnecessary received data, reduce the occurrence of interrupts and the reading of RB, thereby reducing the CPU load. The receiving data setting steps are as follows:

1. Set filter groups.
2. Set RFIE, RAIE and AFWL.
3. Wait for RFIF or RAIF.
4. Read the earliest received data from RB FIFO via RBUF.
5. Set RREL=1 to select the next RB SLOT.
6. Repeat 4, 5 until the RB is confirmed to be empty by RSTAT.

26.4.9 Error handling

On the one hand, CAN_CTRL can automatically handle some errors, such as automatically resending data or discarding received frames containing errors, and on the other hand, reports errors to the CPU through interrupts.

CAN nodes have the following three error states:

- Error Active: The node automatically sends an active error flag when it detects an error.
- Error Passive: A passive error flag is automatically sent when a node detects an error.
- Node closed: In the closed state, this node no longer affects the entire CAN network.

CAN_CTRL provides TECNT and RECNT two counters for counting errors. TECNT and RECNT counters increase or decrease according to the rules stipulated in the CAN2.0B agreement. In addition, a programmable CAN error warning LIMIT register is used to generate an error interrupt to notify the CPU.

There are the following five error types during CAN communication, and the error types can be identified by the KOER bit of the EALCAP register.

- Bit error
- Wrong form

- Filling error
- Wrong answer
- CRC error

26.4.10 Node down

When the number of sending errors is greater than 255, the CAN node automatically enters the node shutdown state and does not participate in CAN communication until it returns to the error active state. The CAN node shutdown status can be confirmed by the BUSOFF bit of the CFG_STAT register. BUSOFF is set and EIF interrupt is generated at the same time.

There are two methods for CAN to recover from the node off state to the error active state:

- Power-on reset
- Received 128 consecutive 11-bit stealth bit sequences (recovery sequence)

In the node shutdown state, the TECNT value remains unchanged, and the RECNT is used for the count recovery sequence. After recovering from node shutdown, TECNT and RECNT are reset to 0.

When the node shutdown flag BUSOFF is set, the RESET bit of the CFG_STAT register is also set.

26.4.11 Lost Arbitration Position Capture

CAN_CTRL can accurately capture the position of the arbitration failure bit and reflect it in the ALC register. The ALC register stores the position of the last arbitration failure bit. If the node wins the arbitration, the ALC bit is not updated.

The ALC value is defined as follows:

After the SOF bit, the first ID data bit ALC is 0, the second ID data bit ALC is 1, and so on. Since arbitration only takes place within the arbitration field, the maximum value of ALC is 31. For example, a standard format remote frame arbitrates with an extended frame, if the extended frame fails at the IDE bit, then ALC=12.

26.4.12 Loop mode

CAN_CTRL supports the following two loopback modes:

- Internal loopback
- External loopback

Both loopback modes can receive data frames sent by themselves, which are mainly used for testing purposes.

In the internal loopback mode, the module internally connects the receiving data line to the sending data line, and the sending data is not output. In internal loopback mode, nodes generate self-acknowledgment signals to avoid ACK errors.

The external loopback mode maintains the connection with the transceiver so that the data sent can still appear on the CAN bus. With the help of the transceiver, CAN can receive the data sent by itself. In the external loopback mode, the SACK bit of the RCTRL register can be used to determine whether to generate a self-acknowledgment signal. When SACK=0, no self-acknowledge signal is generated. When SACK=1, a self-acknowledge signal is generated.

In external loopback mode, when SACK=0, the following two situations will occur:

- Other nodes also receive the data frame sent by the node and send a response signal. In this case, the node can successfully send and receive data.
- If no other node returns an acknowledgment signal, an acknowledgment error is generated, the data is resent and the error counter is incremented. At this time, it is recommended to use the single sending mode.

When returning to normal mode from loopback mode, in addition to clearing the mode bit, a software reset of CAN_CTRL is required.

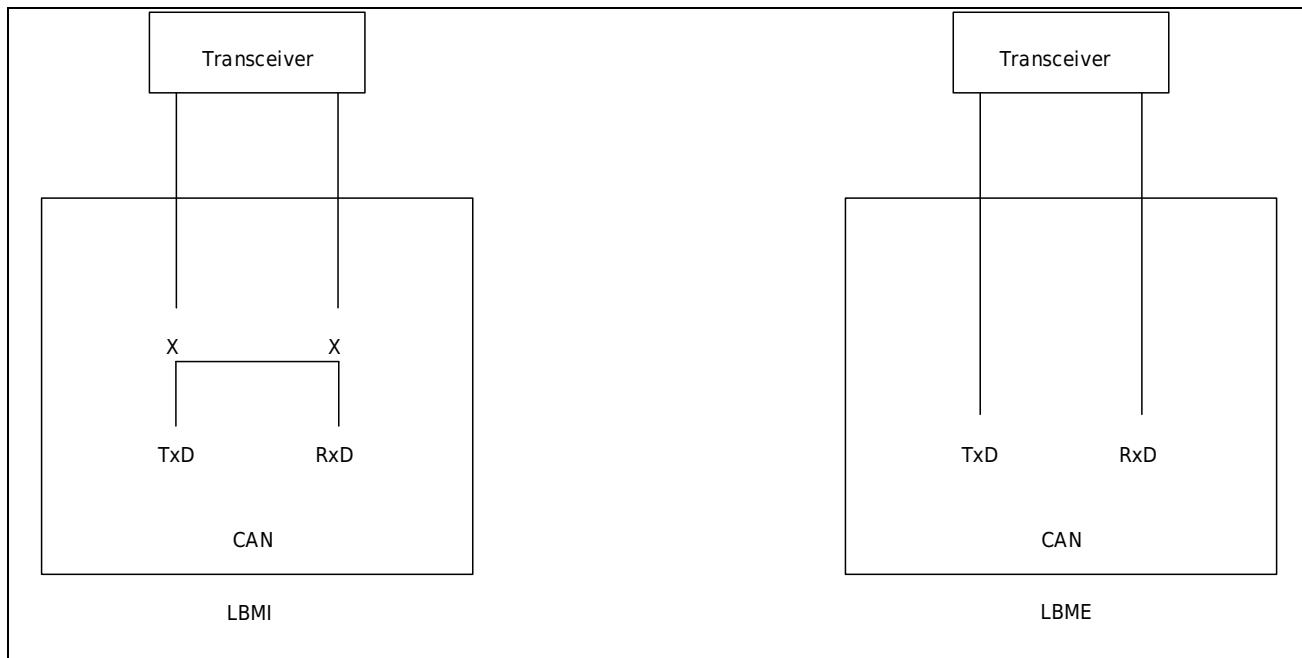

Figure 26-6 Schematic diagram of CAN LBMI and LBME

26.4.13 Silent mode

Silent mode can be used to monitor CAN network data. In silent mode, data can be received from the CAN bus without sending any data to the bus. Set the LOM in the TCMD register to 1 to make the CAN bus controller enter the silent mode, and clear it to 0 to leave the silent mode.

The external loopback mode can be combined with the silent mode to form an external loopback silent mode. At this time, CAN can be regarded as a quiet receiver, but can send data when necessary. In external loopback silent mode, frames containing self-acknowledgment signals are allowed to be sent, but the node does not generate error flags and overload frames.

26.4.14 Software reset function

By setting the RESET bit of the CFG_STAT register to 1, the software reset function is realized. The reset range of the software reset function is shown in the table below.

Table 26-3 Software reset range table

Register bit name	Software reset	Remark	Register bit name	Software reset	Remark
ACFADR	No	-	EWL	Yes	-
ACODE	No	Can only be written by software reset	KOER	Yes	-

TSMODE	No	-			

26.4.15 Upward compatible with CAN-FD function

Even if CAN-CTRL receives CAN-FD frames in a CAN-FD network, the receiver will automatically ignore these frames and not return ACK, and wait until the bus is free before sending or receiving the next CAN2.0B frame.

26.4.16 Time-triggered TTCAN

CAN-CTRL provides partial (level 1) hardware support for the time-triggered communication method specified in ISO11898-4. This chapter introduces TTCAN functions from the following 5 parts.

26.4.16.1 TBUF behavior in TTCAN mode

TTTBM=1

When TTTBM=1, PTB and STB SLOT form TB SLOT as well, and send BUF through the TBPTR register. When TBPTR=0, it points to PTB, TBPTR=1 points to STB SLOT1, and so on. The host can mark the

sending BUF SLOT through the TPE and TPF registers. At this time, the TBSEL and TSNEXT registers have no meaning and can be ignored.

When TTTBM=1, PTB does not have any special attributes. Like STB SLOT, the transmission completion flag also uses TSIF.

In TTCAN mode, there is no FIFO mode and priority arbitration mode for sending BUF, and only one selected SLOT can send data.

In TTCAN mode, time-triggered mode is required for transmission start, TPE, TSONE, TSALL, TPSS and TPA are fixed to 0 and ignored.

TTTB_M=0

When TTTBM=0, use event-driven communication and receive timestamp function in combination. In this mode, the functions of PTB and STB are the same as when TTEN=0, so PTB always has the highest priority, and STB can work in FIFO mode or arbitration mode.

26.4.16.2 TTCAN function description

After power on, Time Master needs to be initialized according to the ISO 11898-4 protocol. In a CAN network, there can be up to 8 potential Time Masters. Each Time Master has its own reference message ID (the last 3 digits of the ID). These potential Time Masters send respective reference messages according to their own priorities.

After TTEN=1, the 16-bit counter starts to work. When the reference message is successfully received or the Time Master successfully sends the reference message, the CAN controller copies Sync_Mark to Ref_Mark, and Ref_Mark sets the cycle time to 0. The successful reception of the reference message sets the RIF flag and the successful transmission of the reference message sets the TPIF flag or the TSIF flag. At this point the host needs to prepare the trigger conditions for the next action.

The trigger condition may be receiving a trigger. This trigger-only interrupt can be used to detect that an expected message has not been received.

The trigger condition can also be a send trigger. This trigger starts sending the data in the TBUF SLOT specified by the TTPTR register. If the selected TBUF SLOT is marked empty, the transmission is not started, but the interrupt flag is set.

26.4.16.3 TTCAN Timing

CAN_CTRL supports ISO11898-4 level 1. A 16-bit counter is included operating at the bit times defined for PRESC, SEG_1, SET_2. If TTEN=1, there is an additional prescaler T_PRESC.

When SOF of one frame of data, the value of the counter is Sync_Mark. If the frame data is a reference message, copy Sync_Mark to Ref_Mark. The cycle time is equal to the value of the counter

minus Ref_Mark. This time is used as a time stamp for receiving messages or as a trigger time reference for sending messages.

26.4.16.4 TTCAN trigger mode

The trigger mode of TTCAN is defined through the TTYPE register, the TTPTR register specifies sending SLOT, and TT_TRIG specifies the cycle time of the trigger.

Contains the following five trigger methods:

- Trigger immediately
- Time trigger
- Single send trigger
- Send start trigger
- Send stop trigger

All triggers use the TTIF flag except the immediate trigger mode. When TTTBM=1, only time trigger mode is supported.

Trigger immediately

By writing the high bit of TT_TRIG (don't care about the value written), the trigger is started. In this mode, the data in the TBUF SLOT selected by TTPTR will be sent immediately. TTIF is not set.

Time trigger

The time trigger mode only generates interrupts by setting the TTIF flag, and has no other functions. Time triggering can be used if a node expects to receive expected data within a specific time window. If the TT_TRIG value is less than the actual cycle time, TEIF is set and there is no other action.

Single send trigger

The one-shot trigger method is used to send data within the execution time window. At this time, the TSSS bit is ignored.

Set the Tick of up to 16 cycle times specified by ISO11898-4 through the TEW bit, and the setting range is 1~16. If data transmission does not start within the specified transmit enable time window, the frame is discarded. The corresponding sending BUF SLOT is marked as empty, and AIF is set, and the data in the corresponding sending BUF will not be rewritten, because it can be sent again by setting TPF.

If the TT_TRIG value is less than the actual cycle time, TEIF is set and there is no other action.

Send start trigger

The sending start trigger mode is used in the arbitration time window to participate in the arbitration. TSSS is used to decide whether to automatically repeat or send a single mode. A send stop trigger can be used to stop the send if the specified message was not sent successfully.

If the TT_TRIG value is less than the actual cycle time, TEIF is set and there is no other action.

Send stop trigger

The send stop trigger method is used to stop the send that has been started by the send start trigger method. If the sending is stopped, the sending frame is discarded, the AIF is set and the selected TBUF SLOT is marked as empty, but the data in the TBUF SLOT will not be rewritten, and it can be sent again by setting the TPF.

If the TT_TRIG value is less than the actual cycle time, TEIF is set and execution stops.

26.4.16.5 TTCAN trigger gate time

The TTCAN trigger watchdog function is similar to the watchdog function and is used when TTTBM=1. Used to watch the time since the last successful reference message received by the gate. The reference message can be received during the cycle time or after an event, and the application should set the appropriate gate time according to the specific situation.

If cycle count is equal to TT_WTRIG, set WTIF. Write 0 by WTIE to disable the gate trigger.

If TT_WTRIG is smaller than the actual cycle time, TEIF is set.

26.4.17 Interrupt

Table 26-4 CAN Interrupt Table

Interrupt logo	Description
RIF	Receive interrupt
ROIF	Receive overflow interrupt
ROIF	Receive BUF full interrupt
RAFIF	Receive BUF will be full interrupt
TPIF	PTB send interrupt
TSIF	STB send interrupt
EIF	error interrupt
AIF	Cancel send interrupt
EPIE	Error passive interrupt
ALIF	Arbitration Lost Interrupt
BEIF	Bus error interrupt
WTIF	Trigger gate interrupt
TEIF	Trigger error interrupt
TTIF	Time triggered interrupt

26.5.1 CAN receive BUF register (CAN_RBUF)

CAN Receive Buffer Registers

Offset address: 0x00~0x0F

Reset value: 0xXXXX XXXX

The RBUF register points to the RB SLOT address of the earliest received CAN mailbox, and the RBUF register can be read in any order.

The KOER bit is the register EALCAP.KOER, which is only meaningful when RBALL=1.

The TX bit indicates that the mailbox sent by itself is received in the loopback mode.

The CYCLE_TIME bit is only valid in TTCAN mode, indicating the cycle time when SOF starts.

The data format of the CAN receiving mailbox is as follows:

Table 26-7 Standard Format CAN Receiving Mailbox Format

Address	b7	b6	b5	b4	b3	b2	b1	b0	Function

The meanings of the control bits are as follows:

IDE(IDentifier Extension):

0: standard format

1: Extended format

RTR(Remote Transmission Request)

0: data frame

1: remote frame

DLC(Data Length Code):

Data length code, the setting range is 0~8, and the corresponding data length is 0Byte~8Byte

26.5.2 CAN transmit BUF register (CAN_TBUF)

CAN Transmit Buffer Registers

Offset address: 0x50~0x5F

Reset value: 0xFFFF XXXX

The TBUF register points to the next empty CAN sending BUF SLOT, and the TBUF register can be read in any order. Write 1 to TSNEXT by software to mark that the corresponding TBUF SLOT has written data, thus pointing to the next TBUF SLOT.

TBUF can only be accessed by WORD.

The data format of the CAN sending mailbox is as follows:

Table 26-9 Standard format CAN sending mailbox format

Address	b7	b6	b5	b4	b3	b2	b1	b0	Function

DLC(Data Length Code):

Data length code, the setting range is 0~8, and the corresponding data length is 0Byte~8Byte

26.5.3 CAN Configuration and Status Register (CAN_CFG_STAT)

CAN Configuration and Status Register

Offset address: 0xA0

Reset value: 0x80

b7	b6	b5	b4	b3	b2	b1	b0
Bit	Marking	Place name	Function				Read and write
b7	RESET	Reset request	reset request bit 0: Do not request a partial reset 1: request partial reset Some registers can only be written when RESET=1. For details, please refer to the software reset function. When the node enters the BUS OFF state, the hardware will automatically set the RESET bit to 1. Please note that it takes 11 CAN bit times for the node to participate in communication when RESET=0.				R/W
b6	LBME	External loopback mode enable bit	External loopback mode enable bit 0: disable external loopback mode 1: Enable external loopback mode Note: It is forbidden to set this bit during communication.				R/W
b5	LBMI	Internal loopback mode enable bit	Internal loopback mode enable bit 0: disable internal loopback mode 1: Enable internal loopback mode Note: It is forbidden to set this bit during communication.				R/W
b4	TPSS	PTB single transfer mode	PTB single transfer mode 0: Disable PTB single transfer mode 1: Enable PTB single transfer mode				R/W
b3	TSSS	STB single transfer mode	STB single transfer mode 0: Disable STB single transfer mode 1: Enable STB single transfer mode				R/W
b2	RACTIVE	Receive status signal	Receive status signal 0: not receiving 1: receiving				R
b1	TACTIVE	Sending status signal	Sending status signal 0: not sending 1: Sending				R
b0	BUSOFF	Bus off state	Bus off state 0: Bus valid state 1: Bus off state NOTE: Writing a 1 clears the TECNT and RECNT registers, but only for debug purposes.				R/W

26.5.4 CAN Command Register (CAN_TCMD)

CAN Command Register

Offset address: 0xA1

Reset value: 0x00

b7	b6	b5	b4	b3	b2	b1	b0
TBSEL	LOM	STBY	TPE	TPA	TSONE	TSALL	TSA

Bit	Marking	Place name	Function	Read and write
b7	TBSEL	Send BUF selection bit	Send BUF selection bit (Transmit Buffer Select) 0: PTB 1: STB When TTEN=1&TTTB=1, TBSEL is reset to reset value. Note: When writing TBUF register or TSNEXT bit, this bit needs to keep a constant value.	R/W
b6	LOM	Silent mode enable bit	Silent mode enable bit (Listen Only Mode) 0: disable silent mode 1: Enable silent mode Sending is prohibited when LOM=1&LBME=0. When LOM=1&LBME=1, it is forbidden to respond to the corresponding received frames and error frames, but it can send data. Note: It is forbidden to set this bit during communication.	R/W
b5	STBY	STBY set bit	STBY set bit 0: Clear STBY 1: Set STBY (TPE, TSONE, TSALL must be 0 before setting)	R/W
b4	TPE	PTB transmit enable bit	PTB send enable bit (Transmit Primary Enable) 0: Disable PTB sending 1: Enable PTB transmission After this bit is enabled, the Mailbox in PTB will be sent at the next available sending position. STB transmissions that have already started will continue, but the next pending STB transmission will be delayed until the PTB transmission is complete. After this bit is written to 1, it will remain 1 until the PTB transmission is completed or the transmission is canceled by TPA. Software cannot clear this bit by writing a 0. The TPE is reset to the reset value by hardware in the following cases: - RESET=1 - BUOFF=1 - LOM=1&LBME=0 - TTEN=1&TTTB=1	R/W
b3	TPA	PTB send cancel bit	PTB send cancel bit (Transmit Primary Abort) 0: do not cancel 1: Cancel the PTB transmission that has been requested by setting TPE to 1 but has not yet started This bit is written 1 by software but cleared by hardware. The TPE bit can be cleared by writing 1, so write 1 at the same time as TPE. The TPE is reset to the reset value by hardware in the following cases: - RESET=1 - BUOFF=1 - TTEN=1&TTTB=1	R/W
b2	TSONE	Send a frame of STB data set bit	Send a frame of STB data set bit (Transmit Secondary ONE frame) 0: do not send 1: Send a frame of STB data In FIFO mode, the earliest written data is sent, and in priority mode, the highest priority data is sent After this bit is written to 1, it will remain 1 until the STB transmission is completed or the transmission is canceled by TSA. Software cannot clear this bit by writing a 0. TSONE is reset to the reset value by hardware in the following cases: - RESET=1 - BUOFF=1 - LOM=1&LBME=0 - TTEN=1&TTTB=1	R/W
b1	TSALL	Send all STB data set bits	Send all STB data set bits (Transmit Secondary ALL frame) 0: do not send 1: Send all data in STB After this bit is written to 1, it will remain 1 until the STB transmission is completed or the transmission is canceled by TSA. Software cannot clear this bit by writing a 0.	R/W

TSALL is reset to the reset value by hardware in the following cases:

- RESET=1
 - BUSOFF=1
 - LOM=1&LBME=0
 - TTEN=1&TTTBIM=1
-

STB send abort bit (Transmit Secondary Abort)

0: do not cancel

1: Cancel the STB transmission that has been requested by TSONE or TSALL but has not yet started

b0 TSA STB sends cancel bit This bit is written 1 by software but cleared by hardware. Write 1 to clear TSONE or TSALL bit. R/W

TSA is reset to the reset value by hardware in the following cases:

- RESET=1
 - BUSOFF=1
-

26.5.5 CAN Transmit Control Register (CAN_TCTRL)

CAN Transmit Control Register

Offset address: 0xA2

Reset value: 0x90

b7	b6	b5	b4	b3	b2	b1	b0
-	TSNEXT	TSMODE	TTTBM	-	-	-	TSSTAT[1:0]

Bit	Marking	Place name	Function	Read and write
b7	Reserved	-	The reset value must be maintained.	R
b6	TSNEXT	Next STB SLOT	Next STB (Transmit buffer Secondary NEXT) 0: no action 1: The current STB SLOT is filled, pointing to the next SLOT After the application program finishes writing the data in TBUF, it indicates that the current STB SLOT has been filled by setting the TSNEXT bit, so that the hardware points TBUF to the next STB SLOT. The data in the STB SLOT identified by the TSNEXT bit can be sent through the TSONE or TSALL bit. This bit is written to 1 by the application program and cleared to 0 by hardware. After all STB SLOTS are filled, TSNEXT remains 1 until a STB SLOT is released. <u>Note: This bit is fixed to 0 in TTCAN mode.</u>	R/W
b5	TSMODE	STB send mode	STB send mode (Transmit buffer Secondary operation MODE) 0: FIFO mode 1: priority mode FIFO mode is sent according to the order in which data frames are written. The priority mode is automatically judged according to the ID. The smaller the ID, the higher the priority. Regardless of the mode, PTB has the highest priority. <u>Note: The TSMODE bit can only be set when the STB is empty.</u>	R/W
b4	TTTBM	TTCAN BUF mode	TTCAN BUF mode (TTCAN Transmit Buffer Mode) When TTEN=0, TTTBM is ignored. 0: TSMODE decision, PTB and STB 1: Set by TBPTR and TTPTR In TTCAN mode, this bit can be set to 0 when only receiving the time stamp function is required, and TSMODE is used to determine whether to use PTB or STB. <u>Note: The TSMODE bit can only be set when the STB is empty.</u>	R/W
b3~b2	Reserved	-	The reset value must be maintained.	R
b1~b0	TSSTAT	STB state	STB status (Transmission Secondary STATus bits) TTEN=0 00: STB empty 01: STB is less than or equal to half full 10: STB is more than half full 11: STB full TTEN=0&TTTBM=1 00: PTB and STB empty 01: PTB and STB are not full 10: reserved 11: PTB and STB full	R

b0	TSFF	Send BUF full flag	TTEN=0 or TTTBM=0: STB full flag (Transmit Secondary buffer Full Flag) 0: STB SLOT is not fully filled 1: STB SLOT is fully filled TTEN=1 and TTTBM=1: TB full flag (Transmit buffer Full Flag) 0: The sending BUF selected by TBPTR is not fully filled 1: The sending BUF selected by TBPTR is fully filled	

26.5.8 CAN Receive and Transmit Interrupt Status Register (CAN_RTIF)

CAN Receive and Transmit Interrupt Status Register

Offset address: 0xA5

Reset value: 0x00

b7	b6	b5	b4	b3	b2	b1	b0
RIF	ROIF	RFIF	RAFIF	TPIF	TSIF	EIF	AIF

Bit	Marking	Place name	Function	Read and write
b7	RIF	Receive interrupt flag	Receive Interrupt Flag (Receive Interrupt Flag) 0: No data frame received 1: A valid data frame or remote frame is received Write 1 to clear 0 by application program.	R/W
b6	ROIF	Receive overflow interrupt flag	Receive overflow interrupt flag (Receive Overrun Interrupt Flag) 0: Receive overflow does not occur 1: Receive overflow occurs Both ROIF and RFIF are set to 1 on overflow. Write 1 to clear 0 by application program.	R/W
b5	RFIF	Receive BUF full interrupt flag	Receive BUF full interrupt flag (RB Full Interrupt Flag) 0: RB FIFO is not full 1: RB FIFO is full Write 1 to clear 0 by application program.	R/W
b4	RAFIF	Receive BUF will be full interrupt flag	Receive BUF will be full interrupt flag (RB Almost Full Interrupt Flag) 0: The number of filled RB SLOTS is less than the AFWL setting value 1: The number of filled RB SLOTS is greater than or equal to the AFWL setting value Write 1 to clear 0 by application program.	R/W
b3	TPIF	PTB send interrupt flag	PTB transmit interrupt flag (Transmission Primary Interrupt Flag) 0: No PTB send completed 1: The requested PTB send completed successfully Write 1 to clear 0 by application program. Note: In TTCAN mode, TPIF is invalid, only the TSIF flag is applicable	R/W
b2	TSIF	STB send interrupt flag	STB transmit interrupt flag (Transmission Secondary Interrupt Flag) 0: No STB transmission completed 1: The requested STB send completed successfully Write 1 to clear 0 by application program. Note: In TTCAN mode, TPIF is invalid, only use TSIF flag	R/W
b1	EIF	Error interrupt flag	Error Interrupt Flag (Error Interrupt Flag) 0: The BUSOFF bit has not changed, or the relative relationship between the error counter value and the ERROR warning limit setting value has not changed. 1: The BUSOFF bit changes, or the relative relationship between the value of the error counter and the setting value of the ERROR warning limit changes. For example, the value of the error counter changes from less than the set value to greater than the set value, or from greater than the set value to less than the set value. Write 1 to clear 0 by application program.	R/W
b0	AIF	Cancel send interrupt flag	Cancel sending interrupt flag (Abort Interrupt Flag) 0: Send data is not canceled 1: The send message requested by TPA and TSA was successfully canceled. Write 1 to clear 0 by application program.	R/W

26.5.9 CAN Error Interrupt Enable and Flags Register (CAN_ERRINT)

CAN ERRor INTerrupt Enable and Flag Register

Offset address: 0xA6

Reset value: 0x00

b7	b6	b5	b4	b3	b2	b1	b0
EWARN	EPASS	WPIE	EPIF	ALIE	ALIF	BEIE	BEIF

Bit	Marking	Place name	Function	Read and write
b7	EWARN	Reached the set ERROR WARNING LIMIT	Reached the set ERROR WARNING LIMIT (Error WARNING limit reached) 0: RECNT or TECNT is less than the set value of EWL 1: RECNT or TECNT is greater than or equal to the EWL setting value Write 1 to clear 0 by application program.	R/W
b6	EPASS	Error passive	Error Passive mode active 0: The node is an active error node 1: Passive error node when node Write 1 to clear 0 by application program.	R
b5	EPIE	Error Passive Interrupt Enable	Error Passive Interrupt Enable (Error Passive Interrupt Enable) 0: Prohibited 1: Enable	R/W
b4	EPIF	Error passive interrupt flag	Error Passive Interrupt Flag (Error Passive Interrupt Flag) 0: No change from error active to error passive or error passive to error active 1: Change from error active to error passive or error passive to error active Write 1 to clear 0 by application program.	R/W
b3	ALIE	Arbitration failure interrupt enable	Arbitration Lost Interrupt Enable (Arbitration Lost Interrupt Enable) 0: Prohibited 1: Enable	R/W
b2	ALIF	Arbitration Lost Interrupt Flag	Arbitration Lost Interrupt Flag (Arbitration Lost Interrupt Flag) 0: Arbitration is successful 1: Arbitration failure Write 1 to clear 0 by application program.	R/W
b1	BEIE	Bus Error Interrupt Enable	Bus Error Interrupt Enable (Bus Error Interrupt Enable) 0: Prohibited 1: Enable	R/W
b0	BEIF	Bus error interrupt flag	Bus Error Interrupt Flag (Bus Error Interrupt Flag) 0: No bus error 1: Bus error Write 1 to clear 0 by application program.	R/W

26.5.10 CAN Bit Timing Register (CAN_BT)

CAN Bit Timing Register

Offset address: 0xA8

Reset value: 0x0102 0203

b15~b0	TT_WTRIG	Trigger time	Trigger time (Trigger Time) Used to specify the cycle time of the gate trigger. When the highest byte of TT_WTRIG is written, the TT_WTRIG value begins to be transferred to the CAN clock domain. Therefore, if BYTE is operated, it is necessary to write the low byte first and then the high byte.	R/W

26.6 Precautions for use

26.6.1 CAN bus anti-jamming measures

The CAN bus is widely used in automobiles, industrial control and other industries. If the electromagnetic environment of the CAN application site is relatively harsh, there are factors such as circuit imbalance, space electromagnetic field, and grid incoming lines, which will cause a large amount of communication noise on the CAN bus due to radiation and conduction interference. , resulting in the increase of bus error frames, frequent retransmissions, and the failure of correct data to arrive in time, which seriously affects the quality of data communication. Therefore, in practical applications, efforts should be made to eliminate noise interference and ensure the stable operation of the CAN bus network.

The following are several commonly used CAN bus anti-interference measures (including but not limited to)

- 1) Increase electrical isolation of CAN bus interface
- 2) Common transceiver signal ground
- 3) Use shielded twisted pair cables and ground them properly
- 4) Improve twisted pair degree of CAN transmission line
- 5) Add signal protector
- 6) Improve network topology
- 7) Application layer software anti-jamming mechanism

26.6.2 CAN Controller Noise Constraints

In the CAN bus network, it should be ensured that the bit time of the communication meets the requirements of the standard protocol. If the noise interference that does not meet the bit time width is introduced, it may cause the abnormal operation of the CAN controller .

27 Analog-to-digital converter (ADC)

27.1 Module Introduction

External analog signals need to be converted into digital signals to be further processed by the MCU. 12-bit successive approximation analog-to-digital converter (SAR ADC) module with high precision and high conversion rate is integrated inside. Has the following properties:

- 12-bit conversion accuracy;
- 1M SPS conversion speed;
- 40 input channels, including 36 external pin inputs, 1-channel internal temperature sensor voltage, 1-channel 1/3 AVCC voltage, and 2-channel DAC outputs;
- 4 reference sources: AVCC voltage, ExRef pin, built-in 1.5V reference voltage, built-in 2.5V reference voltage;
- ADC voltage input range: 0~Vref;
- 4 conversion modes: single conversion, sequential scan continuous conversion, queue scanning continuous conversion, continuous conversion accumulation;
- Input channel voltage threshold monitoring;
- Software can configure ADC conversion rate;
- Built-in signal follower, which can convert high-impedance signals;
- Support on-chip peripherals to automatically trigger ADC conversion, effectively reducing chip power consumption and improving real-time conversion.

27.2 ADC block diagram

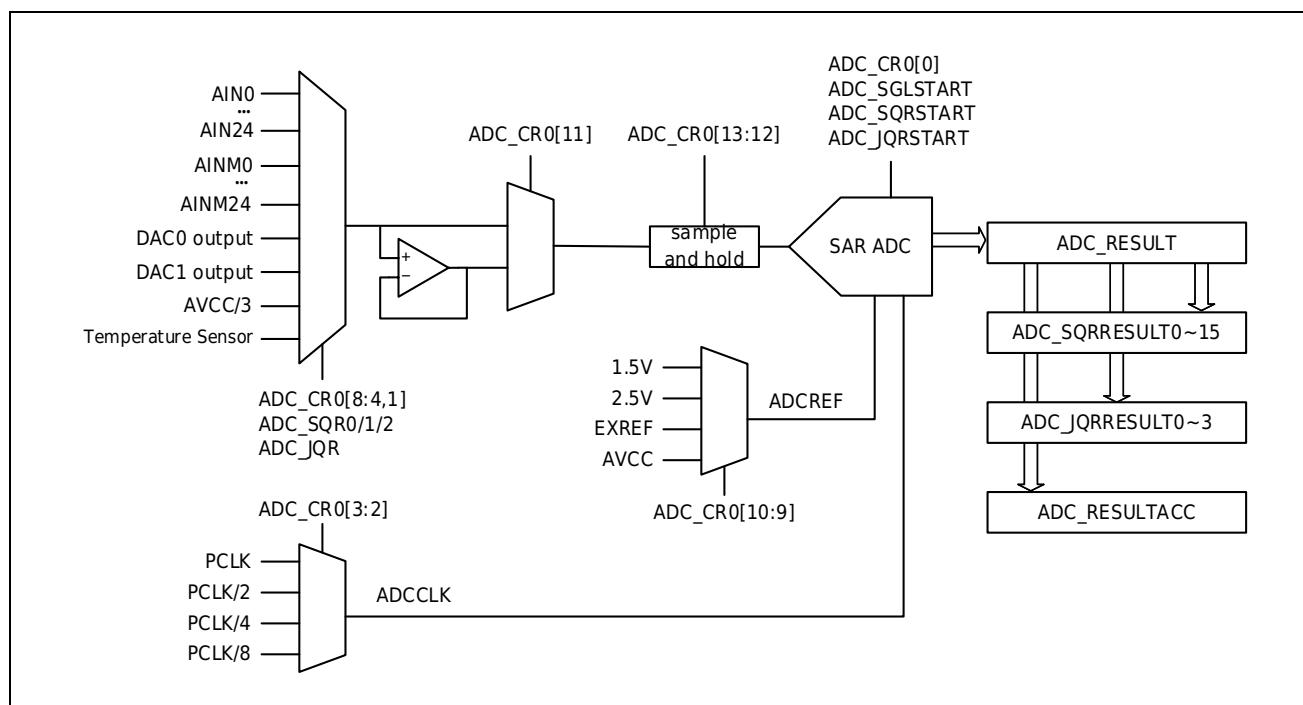

Figure 27-1 ADC block diagram

27.3 Conversion Timing and Conversion Speed

The ADC conversion timing is shown in the figure below: a complete ADC conversion consists of a conversion process and a successive comparison process. Among them, the conversion process requires 4~12 ADCCLKs, which are configured by ADC_CR0.SAM; the successive comparison process requires 16 ADCCLKs. Therefore, an ADC conversion requires a total of 20~ 28 ADCCLKs.

ADC conversion speed is SPS, that is, how many ADC conversions are performed per second. The calculation method of the ADC conversion speed is: the frequency of ADCCLK / the number of ADCCLKs required for one ADC conversion.

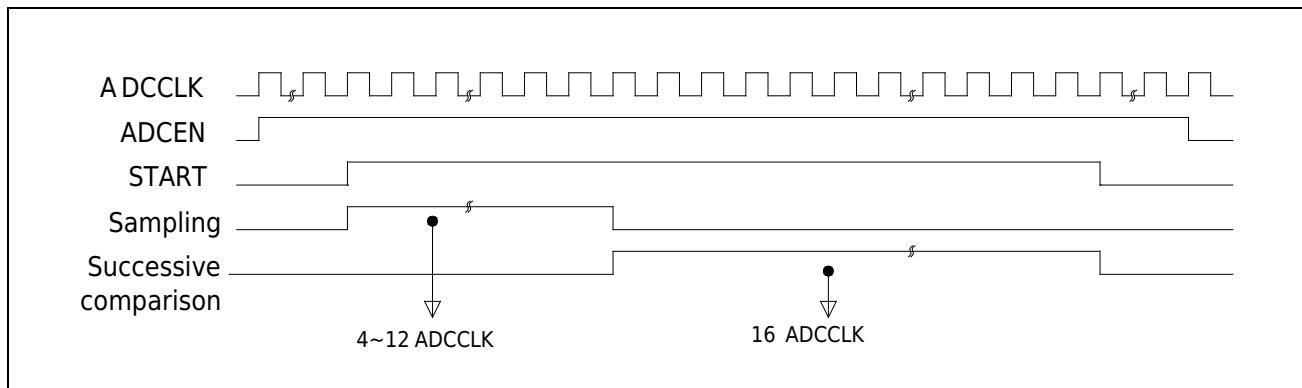

Figure 27-2 ADC conversion timing diagram

The ADC conversion speed is related to the ADC reference voltage and AVCC voltage. The maximum conversion speed is shown in the following table:

ADC reference voltage	AVCC voltage	Maximum conversion speed	Maximum ADCCLK frequency
Internal 1.5V	1.8V~5.5V	200K SPS	4MHz
Internal 2.5V	2.8V~5.5V	200K SPS	4MHz
AVCC / ExRef	1.8V~2.4V	200K SPS	4MHz
AVCC / ExRef	2.4V~2.7V	500K SPS	16MHz
AVCC / ExRef	2.7V~5.5V	1M SPS	24MHz

27.4 Single conversion mode

In the single conversion mode, only one conversion is performed after the ADC starts, and all 30 ADC channels can be converted. This mode can be started by setting the ADC_SglStart.Start bit or by setting the external trigger of ADC_ExtTrigger0. Once the ADC conversion of the selected channel is completed, the ADC_IFR.SGLIF bit is automatically set to 1, and the conversion result is saved in the ADC_Result register.

Start the ADC single conversion operation process through the ADC_SglStart.Start bit:

Step1: Configure the corresponding bits of PAADS~PEADS, and configure the ADC channel to be converted as an analog port.

Step2: Set PBADS.bit1 to 1, and configure the ADC external reference voltage pin as an analog port.

Note: If the ADC reference voltage does not select an external reference voltage pin, this step can be skipped.

Step3: Set BGR_CR.BGR_EN to 1 to enable the BGR module.

Step4: Set ADC_CR0.En to 1 to enable the ADC module.

Step5: Delay 20us, wait for the ADC and BGR module to start up.

Step6: Set ADC_CR1.Mode to 0, select single conversion mode.

Step7: Configure ADC_CR0.Ref to select the reference voltage of ADC.

Step8: Set ADC_CR0.InRefEn to 1 to enable the ADC internal reference voltage.

Note: If the ADC reference voltage does not select the internal reference voltage, this step can be skipped.

Step9: Configure ADC_CR0.SAM and ADC_CR0.CkDiv to set the conversion speed of ADC.

Step10: Configure ADC_CR0.SGLMux and select the channel to be converted.

Step11: Set ADC_ICR.SGLIC to 0 and clear the ADC_IFR.SGLIF flag.

Step12: Set ADC_SglStart.Start to 1 to start ADC single conversion.

Step13: Wait for ADC_IFR.SGLIF to become 1 read the ADC_Result register to get the ADC conversion result.

Step14: To convert other channels, repeat Step10~Step13.

Step15: Set ADC_CR0.En and BGR_CR.BGR_EN to 0, turn off the ADC module and BGR module.

ADC single conversion operation process through an external trigger:

Step1: Configure the corresponding bits of PAADS~PEADS, and configure the ADC channel to be converted as an analog port.

Step2: Set PBADS.bit1 to 1, and configure the ADC external reference voltage pin as an analog port.

Note: If the ADC reference voltage does not select an external reference voltage pin, this step can be skipped.

Step3: Set BGR_CR.BGR_EN to 1 to enable the BGR module.

Step4: Set ADC_CR0.En to 1 to enable the ADC module.

Step5: Delay 20us, wait for the ADC and BGR module to start up.

Step6: Set ADC_CR1.Mode to 0, select single conversion mode.

Step7: Set ADC_CR0.IE to 1 to enable ADC interrupt.

Step8: Enable the ADC interrupt in the NVIC interrupt vector table.

Step9: Configure ADC_CR0.Ref to select the reference voltage of ADC.

Step10: Set ADC_CR0.InRefEn to 1 to enable ADC internal reference voltage.

Note: If the ADC reference voltage does not select the internal reference voltage, this step can be skipped.

- Step11: Configure ADC_CR0.SAM and ADC_CR0.CkDiv to set the conversion speed of ADC.
- Step12: Configure ADC_CR0.SGLMux and select the channel to be converted.
- Step13: Set ADC_IFR to 0x0 clear the ADC interrupt flag.
- Step14: Configure ADC_ExtTrigger0 and select the external trigger condition.
- Step15: When the external trigger condition triggers the ADC to complete the conversion, the ADC module will generate an interrupt. Users can read the ADC_Result register in the ADC interrupt service routine to get the ADC conversion result.
- Step16: To convert other channels, repeat Step12~Step15.
- Step17: Set ADC_CR0.En and BGR_CR.BGR_EN to 0 turn off the ADC module and BGR module.

27.5 Scan conversion mode

The scan conversion mode is divided into two modes: sequential scan conversion and queue scan conversion. When the two modes work independently, multiple conversions can be performed on multiple channels continuously; when the two modes work at the same time, the conversion of the channel configured by jumping in line is given priority.

27.5.1 Sequential Scan Conversion Mode

The sequential scan conversion mode can perform up to 16 consecutive conversions, and the total number of conversions is configured by ADC_SQR2.CNT; all channels can be configured for conversion, and the channel to be converted is configured by ADC_SQRx.CHxMux. This mode can be started by setting the ADC_SqrStart.Start bit or by setting the external trigger of ADC_ExtTrigger0. After starting the conversion, the ADC module converts the channels configured in CHxMux~CH0Mux in turn until the total number of conversions is completed. After the ADC module completes the total number of conversions, the ADC_IFR.SQRIF bit will be automatically set to 1, and the conversion result will be saved in the ADC_SqrResultx~ADC_SqrResult0 register corresponding to the conversion channel. The figure below demonstrates the sequential scan conversion process with 8 conversions for AIN0 AIN1 AIN5. Among them, the sequential scan conversion channels 7, 4, and 1 are configured as AIN1, the conversion channels 6, 3, and 0 are configured as AIN0, and the conversion channels 5 and 2 are configured as AIN5. After ADC_SqrStart.Start is set to 1, the ADC module will convert sequential scan conversion channels 7~0 in turn.

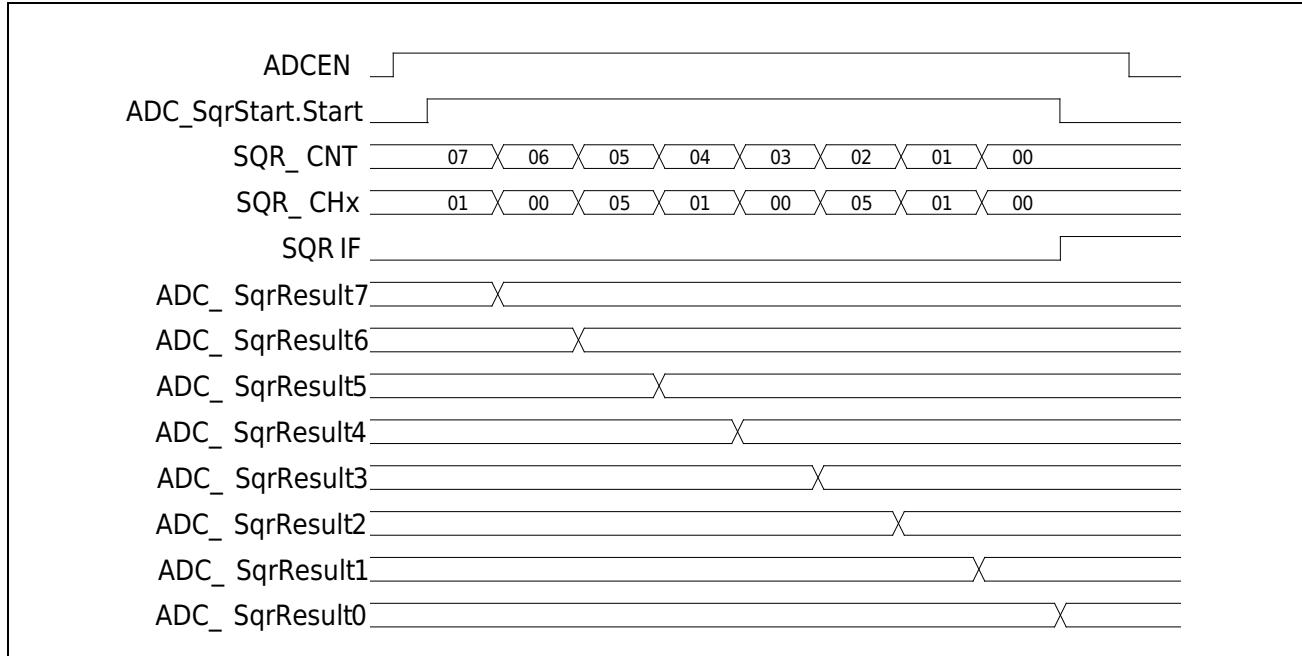

Figure 27-3 ADC sequential scan conversion process example

Start the ADC sequential scan conversion operation process through the ADC_SqrStart.Start bit:

Step1: Configure the corresponding bits of PAADS~PEADS, and configure the ADC channel to be converted as an analog port.

Step2: Set PBADS.bit1 to 1, and configure the ADC external reference voltage pin as an analog port.

Note: If the ADC reference voltage does not select an external reference voltage pin, this step can be skipped.

Step3: Set BGR_CR.BGR_EN to 1 to enable the BGR module.

Step4: Set ADC_CR0.En to 1 to enable the ADC module.

Step5: Delay 20us, wait for the ADC and BGR module to start up.

Step6: Set ADC_CR1.Mode to 1, select scan conversion mode.

Step7: Configure ADC_CR0.Ref to select the reference voltage of ADC.

Step8: Set ADC_CR0.InRefEn to 1 to enable the ADC internal reference voltage.

Note: If the ADC reference voltage does not select the internal reference voltage, this step can be skipped.

Step9: Configure ADC_CR0.SAM and ADC_CR0.CkDiv to set the conversion speed of ADC.

Step10: Configure ADC_SQRx.CHxMux, select the sequential scan conversion channel.

Step11: Configure ADC_SQR2.CNT to select the total number of conversions for sequential scan conversion.

Note: The total number of conversions needs to be consistent with the number of conversion channels configured in Step9.

Step12: Set ADC_ICR.SQRIC to 0, clear the ADC_IFR.SQRIIF flag

- Step13: Set ADC_SqrStart.Start to 1 to start ADC sequential scan conversion.
- Step14: Wait for ADC_IFR.SQRIF to become 1, read the ADC_SqrResultx ~ ADC_SqrResult0 registers to obtain the conversion result of the corresponding channel.
- Step15: To convert other channels, repeat Step10~Step14.
- Step16: Set ADC_CR0.En and BGR_CR.BGR_EN to 0 turn off the ADC module and BGR module.

Start the ADC sequential scan conversion operation process through an external trigger:

Step1: Configure the corresponding bits of PAADS~PEADS, and configure the ADC channel to be converted as an analog port.

Step2: Set PBADS.bit1 to 1, and configure the ADC external reference voltage pin as an analog port.

Note: If the ADC reference voltage does not select an external reference voltage pin, this step can be skipped.

Step3: Set BGR_CR.BGR_EN to 1 to enable the BGR module.

Step4: Set ADC_CR0.En to 1 to enable the ADC module.

Step5: Delay 20us, wait for the ADC and BGR module to start up.

Step6: Set ADC_CR1.Mode to 1, select scan conversion mode.

Step7: Set ADC_CR0.IE to 1 to enable ADC interrupt.

Step8: Enable the ADC interrupt in the NVIC interrupt vector table.

Step9: Configure ADC_CR0.Ref to select the reference voltage of ADC.

Step10: Set ADC_CR0.InRefEn to 1 to enable ADC internal reference voltage.

Note: If the ADC reference voltage does not select the internal reference voltage, this step can be skipped.

Step11: Configure ADC_CR0.SAM and ADC_CR0.CkDiv to set the conversion speed of ADC.

Step12: Configure ADC_SQRx.CHxMux, select the sequential scan conversion channel.

Step13: Configure ADC_SQR2.CNT to select the total number of conversions for sequential scan conversion.

Note: The total number of conversions needs to be consistent with the number of conversion channels configured in Step11.

Step14: Set ADC_IFR to 0x0, clear the ADC interrupt flag.

Step15: Configure ADC_ExtTrigger0 and select the external trigger condition.

Step16: When the external trigger condition triggers the ADC to complete the conversion, the ADC module will generate an interrupt. Users can read the ADC_SqrResultx ~ ADC_SqrResult0 registers in the ADC interrupt service routine to get the conversion result of the corresponding channel.

Step17: To convert other channels, repeat Step12~Step16.

Step18: Set ADC_CR0.En and BGR_CR.BGR_EN to 0 turn off the ADC module and BGR module.

27.5.2 In-queue scan conversion mode

The jump scan conversion mode can perform up to 4 consecutive conversions, and the total number of conversions is configured by ADC_JQR.CNT; all channels can be configured for conversion, and the channel to be converted is configured by ADC_JQR.CHxMux. This mode can be started by setting the ADC_JqrStart.Start bit or by setting the external trigger of ADC_ExtTrigger1. After starting the conversion, the ADC module converts the channels configured in CHxMux~CH0Mux in turn until the total number of conversions is completed. After the ADC module completes the total number of conversions, the ADC_IFR.JQRIF bit will be automatically set to 1, and the conversion result will be stored in the ADC_JqrResultx~ ADC_JqrResult0 registers corresponding to the conversion channel. The figure below demonstrates the process of performing 4 conversions of AIN0, AIN1, and AIN5 in the queue scan conversion process. Among them, the queue scanning conversion channels 3, 2, 1, and 0 are respectively set to AIN5, AIN0, AIN1, and AIN5. After ADC_JqrStart.Start is set to 1, the ADC module will sequentially convert the queue scanning conversion channels 3~0.

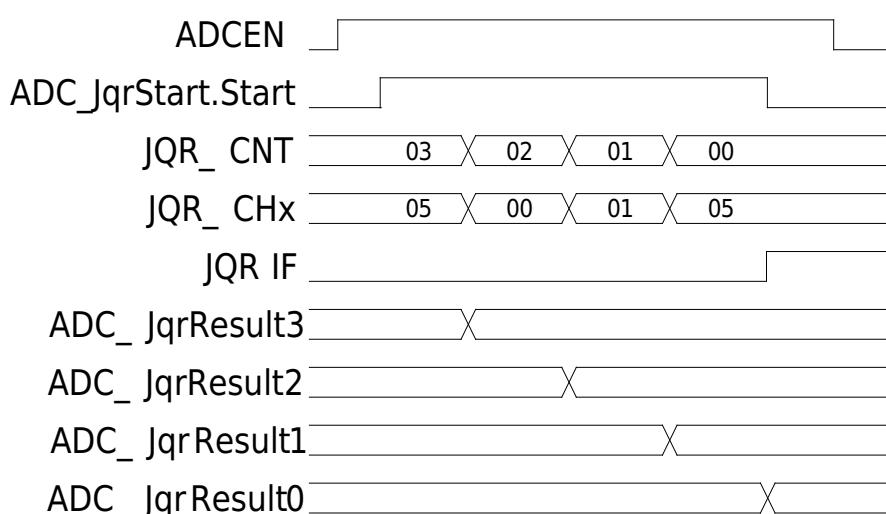

Figure 27-4 ADC skipping scan conversion process example -

Start the ADC jump-in scan conversion operation process through the ADC_JqrStart.Start bit:

Step1: Configure the corresponding bits of PAADS~PCADS, and configure the ADC channel to be converted as an analog port.

Step2: Set PBADS.bit1 to 1, and configure the ADC external reference voltage pin as an analog port.

Note: If the ADC reference voltage does not select an external reference voltage pin, this step can be skipped.

Step3: Set BGR_CR.BGR_EN to 1 to enable the BGR module.

Step4: Set ADC_CR0.En to 1 to enable the ADC module.

Step5: Delay 20us, wait for the ADC and BGR module to start up.

Step6: Set ADC_CR1.Mode to 1, select scan conversion mode.

Step7: Configure ADC_CR0.Ref to select the reference voltage of ADC.

Step8: Set ADC_CR0.InRefEn to 1 to enable the ADC internal reference voltage.

Note: If the ADC reference voltage does not select the internal reference voltage, this step can be skipped.

Step9: Configure ADC_CR0.SAM and ADC_CR0.CkDiv to set the conversion speed of ADC.

Step10: Configure ADC_JQR.CHxMux and select the queue-jumping scan conversion channel.

Step11: Configure ADC_JQR.CNT to select the total number of conversions for queue jump scan conversion.

Note: The total number of conversions needs to be consistent with the number of conversion channels configured in Step9.

Step12: Set ADC_ICR.JQRIC to 0 and clear the ADC_IFR.JQRIF flag.

Step13: Set ADC_JqrStart.Start to 1 to start ADC jump-in scan conversion.

Step14: Wait for ADC_IFR.JQRIF to become 1, and read the ADC_JqrResultx~ADC_JqrResult0 registers to obtain the conversion result of the corresponding channel.

Step15: To convert other channels, repeat Step10~Step14.

Step16: Set ADC_CR0.En and BGR_CR.BGR_EN to 0 turn off the ADC module and BGR module.

Start the ADC queue-queue scan conversion operation process through an external trigger:

Step1: Configure the corresponding bits of PAADS~PCADS, and configure the ADC channel to be converted as an analog port.

Step2: Set PBADS.bit1 to 1, and configure the ADC external reference voltage pin as an analog port.

Note: If the ADC reference voltage does not select an external reference voltage pin, this step can be skipped.

Step3: Set BGR_CR.BGR_EN to 1 to enable the BGR module.

Step4: Set ADC_CR0.En to 1 to enable the ADC module.

Step5: Delay 20us, wait for the ADC and BGR module to start up.

Step6: Set ADC_CR1.Mode to 1, select scan conversion mode.

Step7: Set ADC_CR0.IE to 1 to enable ADC interrupt.

Step8: Enable the ADC interrupt in the NVIC interrupt vector table.

Step9: Configure ADC_CR0.Ref to select the reference voltage of ADC.

Step10: Set ADC_CR0.InRefEn to 1 to enable ADC internal reference voltage.

Note: If the ADC reference voltage does not select the internal reference voltage, this step can be skipped.

Step11: Configure ADC_CR0.SAM and ADC_CR0.CkDiv to set the conversion speed of ADC.

Step12: Configure ADC_JQR.CHxMux, and select the queue-to-scan conversion channel.

Step13: Configure ADC_JQR.CNT to select the total number of conversions for queue jump scan conversion.

Note: The total number of conversions needs to be consistent with the number of conversion channels configured in Step11.

Step14: Set ADC_IFR to 0x0, clear the ADC interrupt flag.

Step15: Configure ADC_ExtTrigger1 and select the external trigger condition.

Step16: When the external trigger condition triggers the ADC to complete the conversion, the ADC module will generate an interrupt. Users can read the ADC_JqrResultx~ADC_JqrResult0 registers in the ADC interrupt service routine to get the conversion result of the corresponding channel.

Step17: To convert other channels, repeat Step12~Step16.

Step18: Set ADC_CR0.En and BGR_CR.BGR_EN to 0 turn off the ADC module and BGR module.

The execution priority of the jump scan conversion is higher than that of the sequential scan conversion. When the sequential scan conversion is in progress, if the queue scan conversion is started, the sequential scan will be suspended after the conversion of the current channel is completed, and then continue to execute the rest after the queue scan conversion is completed. Channel conversion below. The figure below demonstrates the process of starting the queue-hopping scan conversion for AIN2 and AIN6 when performing sequential scan conversion on AIN0, AIN1, AIN5, and AIN8. Among them, sequential scan conversion channels 3, 2, 1, and 0 are set to AIN1, AIN0, AIN5, and AIN8 respectively, and queue-cutting scan conversion channels 1 and 0 are respectively set to AIN6 and AIN2. In the process of sequential scanning for AIN0 conversion, the queue scanning is started. The sequential scanning will complete the conversion of the current AIN0 and then pause. After the queue scanning completes the conversion of AIN6 and AIN2, the sequential scanning will perform the conversion of AIN5 and AIN8.

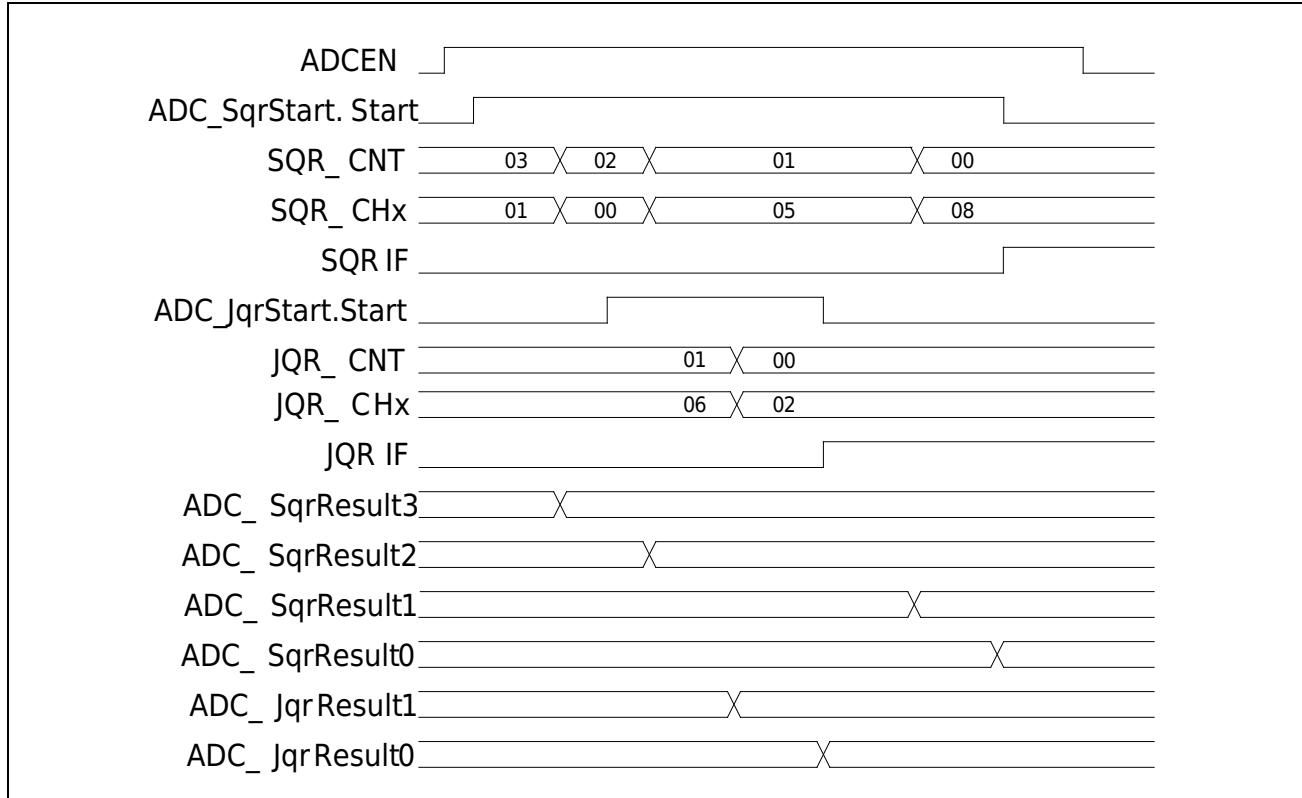

Figure 27-5 Example of skipping scan during ADC sequential scan

27.5.3 Scan conversion triggers DMA read

After the conversion of sequential scan and skip scan is completed, the DMA can be automatically triggered to read the conversion result. In the sequential scan mode, enable this function by configuring ADC_CR1.DmaSqr to 1; in the jump scan mode, enable this function by configuring ADC_CR1.Dmajqr as 1.

27.6 Continuous Conversion Accumulation Mode

In the continuous conversion and accumulation mode, starting the ADC once can perform multiple conversions on multiple channels and accumulate the results of each conversion; all channels can be configured to convert. The total number of ADC conversions is configured by ADC_SQR2.CNT; the channel to be converted is configured by ADC_SQRx.CHxMux. This mode can be started by setting the ADC_SqrStart.Start bit or by setting the external trigger of ADC_ExtTrigger0. After starting the continuous conversion, the ADC module converts the channels configured in CHxMux~CH0Mux in turn until the total number of conversions is completed. After the ADC module completes the total number of conversions, the ADC_IFR.SQRIF bit is automatically set to 1, and the accumulated value of the conversion result is stored in the ADC_ResultAcc register.

The figure below demonstrates the process of accumulating 10 consecutive conversions of AIN0, AIN1, and AIN5. Sequential scan conversion channels 9, 6, 3, 0 are configured as AIN0, conversion channels 8, 5, 2 are configured as AIN1, and conversion channels 7, 4, 1 are configured as AIN5.

After ADC_SqrStart.Start is set to 1, the ADC module will convert sequentially according to the sequential scan conversion channel configuration until the count value of SQR_CNT becomes 0. The ADC_ResultAcc register is automatically accumulated each time a conversion is complete. The conversion results of AIN0, AIN1, and AIN5 given in the figure are 0x010, 0x020, and 0x040 in turn.

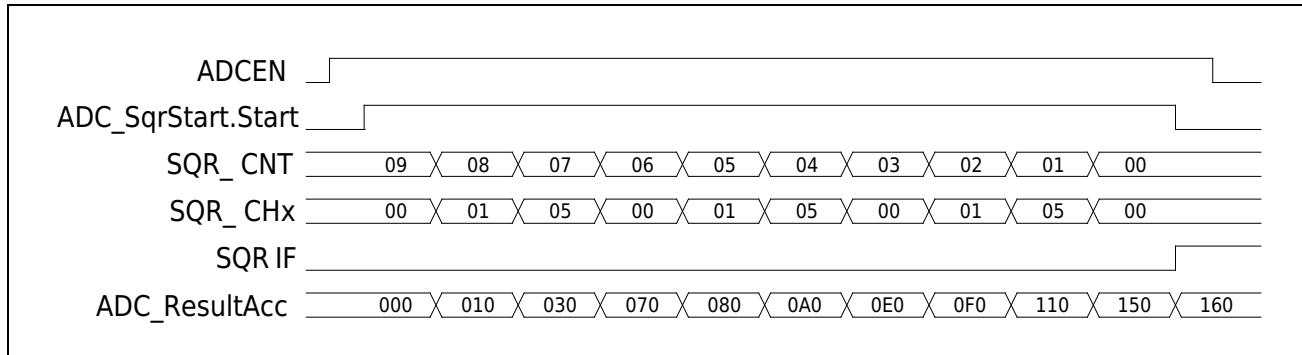

Figure 27-6 ADC Continuous Conversion Accumulation Process Example

Start the ADC continuous conversion and accumulation operation process through the ADC_SqrStart.Start bit:

Step1: Configure the corresponding bits of PAADS~PEADS, and configure the ADC channel to be converted as an analog port.

Step2: Set PBADS.bit1 to 1, and configure the ADC external reference voltage pin as an analog port.

Note: If the ADC reference voltage does not select an external reference voltage pin, this step can be skipped.

Step3: Set BGR_CR.BGR_EN to 1 to enable the BGR module.

Step4: Set ADC_CR0.En to 1 to enable the ADC module.

Step5: Delay 20us, wait for the ADC and BGR module to start up.

Step6: Set ADC_CR1.Mode to 1, select scan conversion mode.

Step7: Set ADC_CR1.RAccEn to 1 to enable the automatic accumulation function of ADC conversion.

Step8: Configure ADC_CR0.Ref to select the reference voltage of ADC.

Step9: Set ADC_CR0.InRefEn to 1 to enable ADC internal reference voltage.

Note: If the ADC reference voltage does not select the internal reference voltage, this step can be skipped.

Step10: Configure ADC_CR0.SAM and ADC_CR0.CkDiv to set the conversion speed of ADC.

Step11: Configure ADC_SQRx.CHxMux, select the sequential scan conversion channel.

Step12: Configure ADC_SQR2.CNT to select the total number of conversions for sequential scan conversion.

Note: The total number of conversions needs to be consistent with the number of conversion channels configured in Step10.

Step13: Set ADC_ICR.SQRIC to 0 and clear the ADC_IFR.SQRIF flag.

- Step14: Set ADC_CR1.RAccClr to 0, and clear the ADC_ResultAcc register.
- Step15: Set ADC_SqrStart.Start to 1 to start ADC sequential scan conversion.
- Step16: Wait for ADC_IFR.SQRIF to become 1, and read the ADC_ResultAcc register to obtain the accumulated value of the conversion result.
- Step17: To convert other channels, repeat Step11~Step16.
- Step18: Set ADC_CR0.En and BGR_CR.BGR_EN to 0 turn off the ADC module and BGR module.

Start ADC continuous conversion and accumulation operation process through external trigger:

Step1: Configure the corresponding bits of PAADS~PEADS, and configure the ADC channel to be converted as an analog port.

Step2: Set PBADS.bit1 to 1, and configure the ADC external reference voltage pin as an analog port.

Note: If the ADC reference voltage does not select an external reference voltage pin, this step can be skipped.

Step3: Set BGR_CR.BGR_EN to 1 to enable the BGR module.

Step4: Set ADC_CR0.En to 1 to enable the ADC module.

Step5: Delay 20us, wait for the ADC and BGR module to start up.

Step6: Set ADC_CR1.Mode to 1, select scan conversion mode.

Step7: Set ADC_CR0.IE to 1 to enable ADC interrupt.

Step8: Enable the ADC interrupt in the NVIC interrupt vector table.

Step9: Set ADC_CR1.RAccEn to 1 to enable the automatic accumulation function of ADC conversion.

Step10: Configure ADC_CR0.Ref to select the reference voltage of ADC.

Step11: Set ADC_CR0.InRefEn to 1 to enable ADC internal reference voltage.

Note: If the ADC reference voltage does not select the internal reference voltage, this step can be skipped.

Step12: Configure ADC_CR0.SAM and ADC_CR0.CkDiv to set the conversion speed of ADC.

Step13: Configure ADC_SQRx.CHxMux, select the sequential scan conversion channel.

Step14: Configure ADC_SQR2.CNT to select the total number of conversions for sequential scan conversion.

Note: The total number of conversions needs to be consistent with the number of conversion channels configured in Step12.

Step15: Set ADC_IFR to 0x0, clear the ADC interrupt flag.

Step16: Set ADC_CR1.RAccClr to 0, and clear the ADC_ResultAcc register.

Step17: Configure ADC_ExtTrigger0 and select the external trigger condition.

Step18: When the external trigger condition triggers the ADC to complete the conversion, the ADC module will generate an interrupt. Users can read the ADC_ResultAcc register in the ADC interrupt service routine to get the conversion result accumulation value.

Step19: To convert other channels, repeat Step13~Step18.

Step20: Set ADC_CR0.En and BGR_CR.BGR_EN to 0 turn off the ADC module and BGR module.

27.7 ADC conversion external trigger source

ADC conversions can be initiated either by software configuration or by an external trigger.

Configure the ADC_ExtTrigger0 register to set the external trigger source for ADC single conversion or sequential scan conversion.

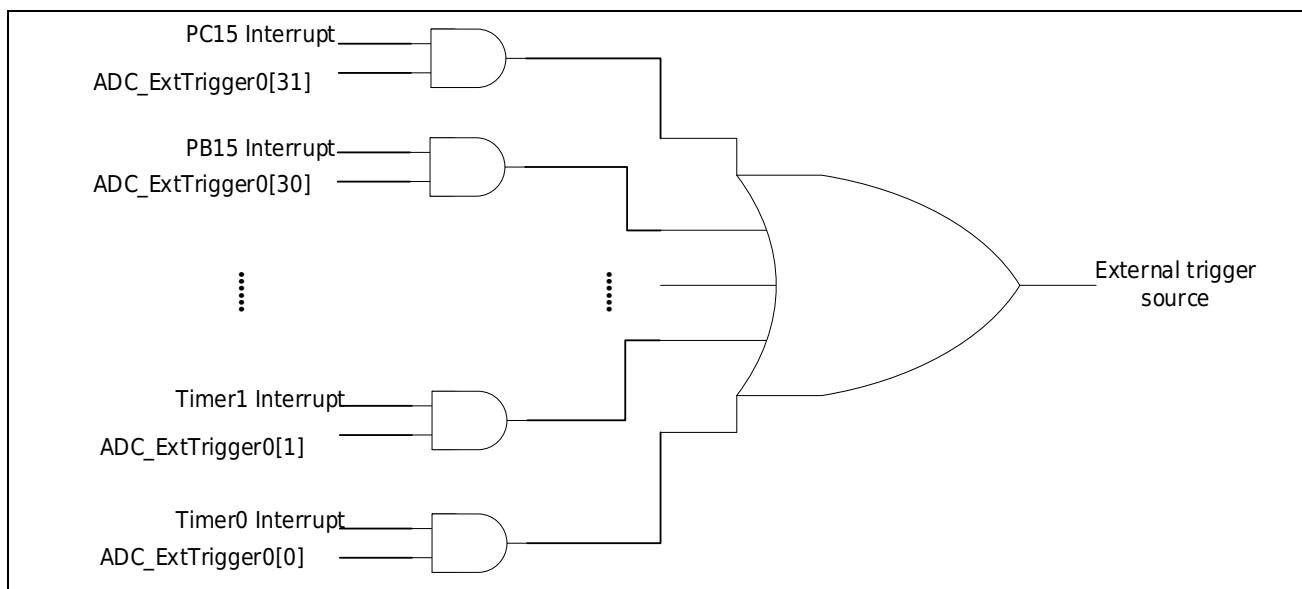

Figure 27-7 Schematic diagram of ADC single conversion or sequential scan conversion external trigger source

Configure the ADC_ExtTrigger1 register to set the external trigger source for ADC jump-in scan conversion.

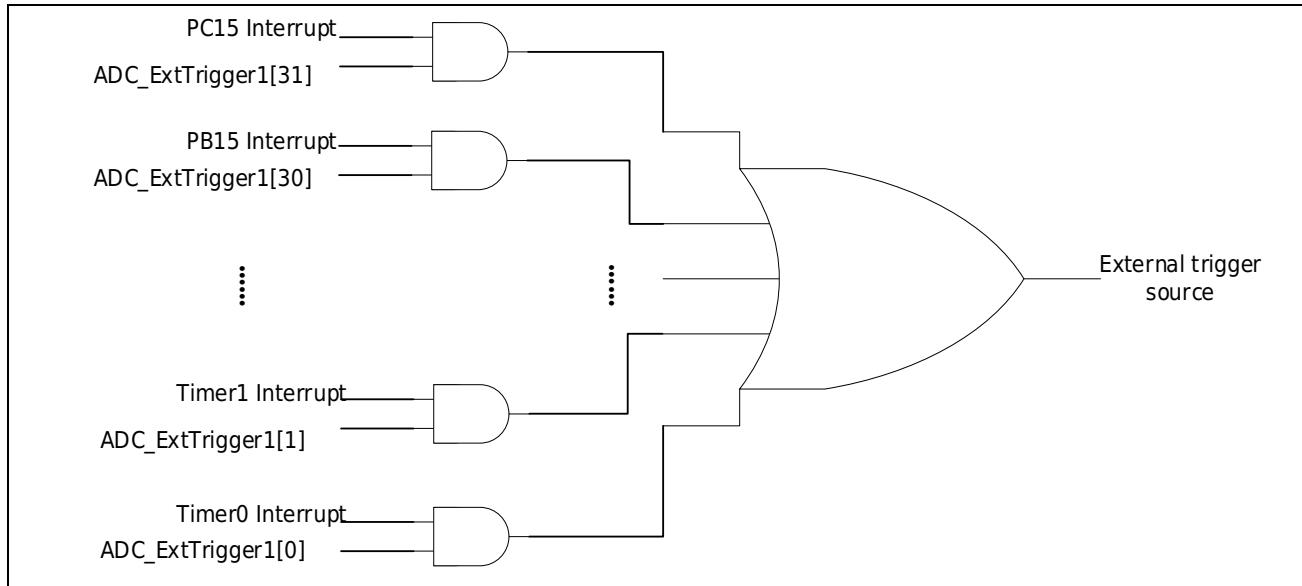

Figure 27-8 Schematic diagram of external trigger source for ADC jumping scan conversion

27.8 ADC conversion result comparison

When the ADC conversion is completed, the ADC conversion result can be compared with the threshold set by the user, supporting upper threshold comparison, lower threshold comparison, and interval value comparison. This function needs to set the corresponding control bits HtCmp, LtCmp, RegCmp to 1. This function can realize the automatic monitoring of the analog quantity, until the ADC conversion result meets the user's expectations, an interrupt is generated to apply for user program interface entry. The monitoring channel selection is configured through ADC_CR1.ThCh.

Upper threshold comparison: When the ADC conversion result is within the range [ADC_LT, 4095], ADC_IFR.HTIF is set to 1; writing 0 to ADC_ICR.HTIC clears ADC_IFR.HTIF.

Lower threshold comparison: When the ADC conversion result is within the range [0, ADC_LT], ADC_IFR.LTIF is set to 1; writing 0 to ADC_ICR.LTIC clears ADC_IFR.LTIF.

Interval value comparison: When the ADC conversion result is within the [ADC_LT, ADC_Ht] interval, ADC_IFR.REGIF is set to 1; writing 0 to ADC_ICR.REGIC clears ADC_IFR.REGIF.

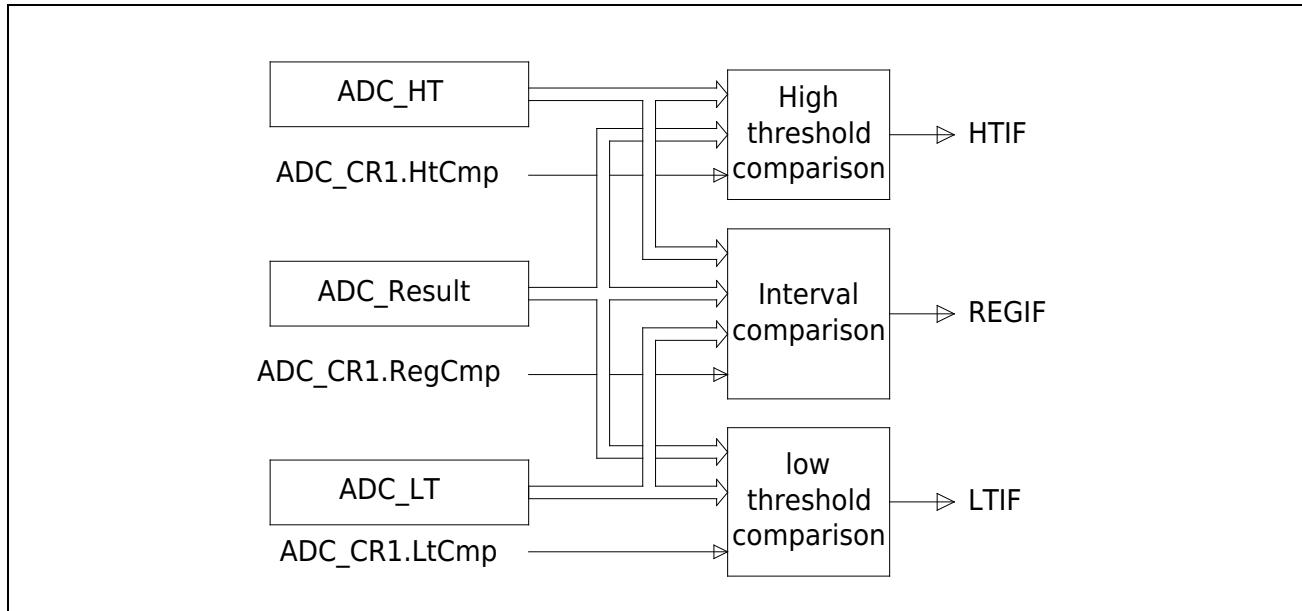

Figure 27-9 ADC conversion result

27.9 ADC Interrupt

The ADC interrupt request is shown in the table below:

Interrupt source	Interrupt logo	Interrupt enable
ADC jump queue scan conversion completed	ADC_IFR.JQRIF	ADC_CR0.IE
ADC sequential scan conversion complete	ADC_IFR.SQRIF	
The ADC conversion result is in the interval value area (greater than or equal to the lower threshold and less than the upper threshold)	ADC_IFR.REGIF	
The ADC conversion result is in the upper threshold region (greater than or equal to the upper threshold)	ADC_IFR.HTIF	
ADC conversion result comparison lower threshold area (less than lower threshold)	ADC_IFR.LTIF	
ADC single conversion completed	ADC_IFR.SGLIF	

27.10 Measure ambient temperature using a temperature sensor

The output voltage of the temperature sensor will change with the change of the ambient temperature, so the corresponding ambient temperature can be calculated according to the output voltage of the temperature sensor. When the measurement channel of the ADC module selects the output voltage of the temperature sensor, the ambient temperature can be measured.

Calculated as follows:

$$\text{Ambient Temperature} = 25 + 0.0854 \times V_{ref} \times (\text{AdcValue} - \text{Trim})$$

Among them: V_{ref} is the reference voltage of the current ADC module, and the value is 1.5 or 2.5.

AdcValue is the result of measuring the output voltage of the temperature sensor by the ADC module, and the value is 0~4095.

Trim is a calibration value of 16Bits, which needs to be read from the Flash memory during calculation, and its storage address is detailed in the table below.

ADC reference voltage	Calibration value storage address	Calibration value accuracy
Internal 1.5V	0x00100C34	±3°C
Internal 2.5V	0x00100C36	±3°C

An example calculation is as follows:

Condition 1: Vref=2.5, AdcValue=0x7E5, Trim=0x76C:

Temperature 1: $25 + 0.0854 \times 2.5 \times (0x7E5 - 0x76C) = 50.8 \text{ }^{\circ}\text{C}$.

Condition 2: Vref=1.5, AdcValue=0x72D, Trim=0x76C:

Temperature 2: $25 + 0.0854 \times 1.5 \times (0x72D - 0x76C) = 16.9 \text{ }^{\circ}\text{C}$.

Operation process of measuring ambient temperature through ADC:

Step1: Set BGR_CR to 3, enable BGR module and temperature sensor module.

Step2: Set ADC_CR0.En to 1 to enable the ADC module.

Step3: Delay 20us, wait for the ADC and BGR module to start up.

Step4: Set ADC_CR1.Mode to 0, select single conversion mode.

Step5: Set ADC_CR0.InRefEn to 1 to enable ADC internal reference voltage.

Step6: Configure ADC_CR0.Ref, select the reference voltage of ADC as internal 1.5V or internal 2.5V.

Step7: Configure ADC_CR0.SAM and ADC_CR0.CkDiv to set the conversion speed of ADC.

Step8: Set ADC_CR0.SGLMux to 0x1C, and select the channel to be converted as the output of the temperature sensor.

Step9: Set ADC_CR0.Buf to 1 to enable the input signal amplifier.

Step10: Set ADC_ICR.SGLIC to 0 and clear the ADC_IFR.SGLIF flag.

Step11: Set ADC_SglStart.Start to 1 to start ADC single conversion.

Step12: Wait for ADC_IFR.SGLIF to become 1, read the ADC_Result register to get the ADC conversion result.

Step13: Set ADC_CR0.En and BGR_CR to 0, turn off the ADC module, BGR module, and temperature sensor module.

Step14: Read the calibration value of the temperature sensor and calculate the current ambient temperature according to the formula.

28 Digital to Analog Converter (DAC)

The DAC module is a 12-bit voltage output digital-to-analog converter. The DAC can be configured in 8-bit or 12-bit mode and can be used with a DMA controller. In 12-bit mode, data can be left-justified or right-justified. Input reference voltage VREF+ (shared with ADC) can be used. The output can be optionally buffered for higher current drive.

28.1 DAC Characteristic

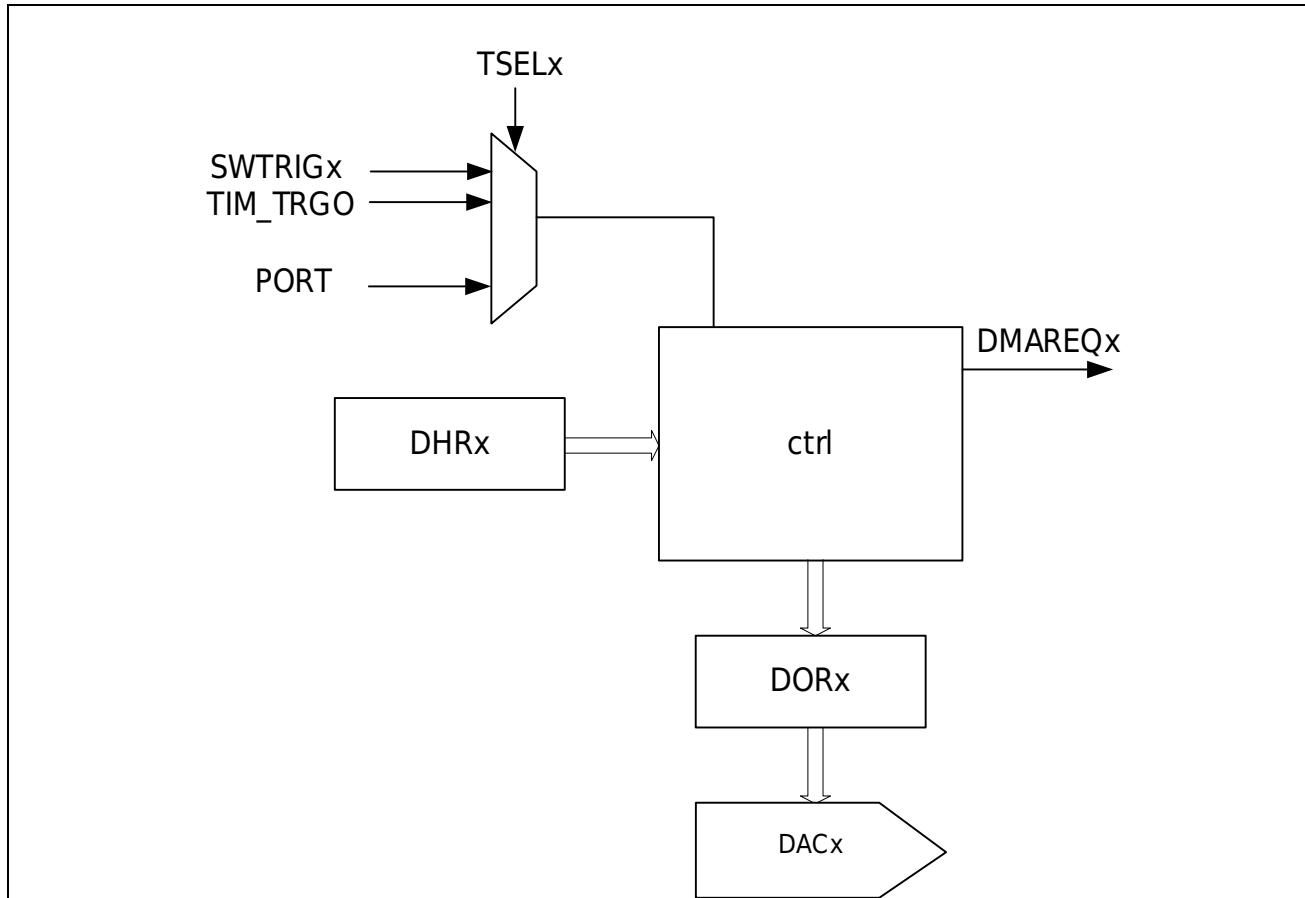

The device integrates two DAC converters, each with one output channel: DAC0_OUT and DAC1_OUT.

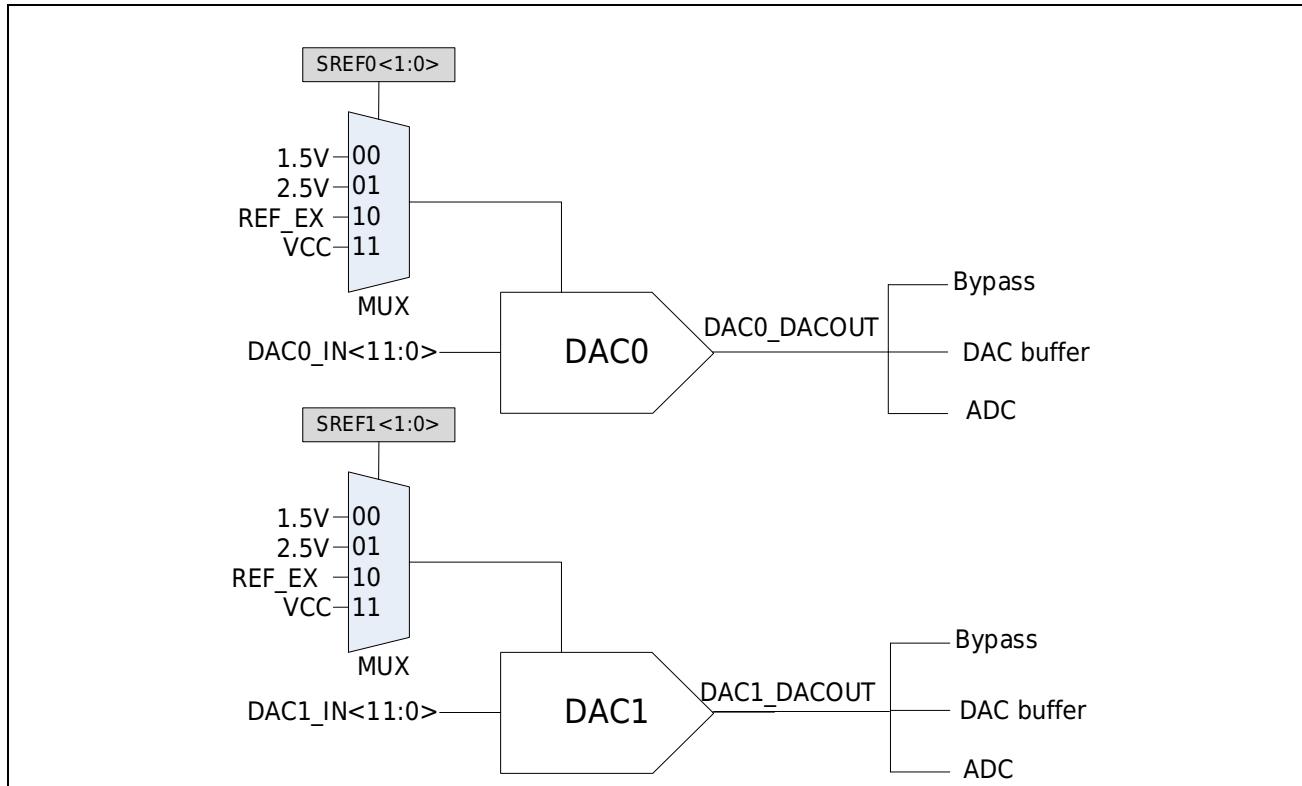

The main features of the DAC are as follows:

- A data holding register
- Data is left-justified or right-justified in 12-bit mode
- Synchronous update function
- Generate noise
- Generate triangle wave
- Dual DAC channels, support separate or simultaneous conversion
- DMA functions (including underflow detection)
- Conversion via external trigger signal
- 4 reference sources: AVCC voltage, ExRef pin, built-in 1.5v reference voltage, built-in 2.5v reference voltage;

28.2 Functional description

28.2.1 Block diagram

28.2.2 DAC output buffer enable

The DAC can use an output buffer, which can be used to reduce the output impedance and directly drive an external load without adding an external operational amplifier. For the settings of the output buffer, refer to the chapter < Operational Amplifier OPA>

DAC channel output buffer can be enabled or disabled via the BOFF1 bit in the DAC_CR register.

28.2.3 DAC channel enable

DAC channel can be enabled by setting the corresponding ENx bit in the DAC_CR register to 1. After a period of startup tWAKEUP, each DAC channel is actually enabled.

The ENx bits only enable the analog DAC channel x units. Even if the ENx bit is reset, the DAC channel x digital interface is still enabled.

28.2.4 DAC output voltage

After a linear conversion, the digital input is converted to an output voltage between 0 and VREF+. The analog output voltage at each DAC channel pin is determined by the following formula:

$$\text{DAC}_{\text{out}} = \text{V}_{\text{ref}} * \text{ DOR}/4096$$

28.2.5 DAC trigger selection

If the TENx control bit is set, the conversion can be triggered by an external event (timer counter, external interrupt line) or software. The TSELx[2:0] control bits will determine which possible event will trigger the conversion as shown in the table below.

TSEL	000	001	010	011	100	101	110	111
Trigger source	TIM0 TRADC	TIM1 TRADC	TIM2 TRADC	TIM3 TRADC	TIM4 TRADC	TIM5 TRADC	SW TRIG	EXTI

Whenever a rising edge is detected on the DAC selected timer TRGO output or on the selected external port trigger, the last data stored in the DAC_DHRx register is transferred to the DAC_DORx register. APB1 cycles after the trigger, the DAC_DORx registers will be updated.

If software triggering is selected, the conversion starts as soon as the SWTRIG bit is set. After the DAC_DHRx register contents are loaded into the DAC_DORx register, SWTRIG is reset by hardware.

Note:

- The TSELx[2:0] bits cannot be changed while the ENx bit is set. If software triggering is selected, the contents of the DAC_DHRx registers are transferred to the DAC_DORx registers in only one APB1 clock cycle.

28.2.6 Single mode function description

28.2.6.1 DAC data format

Depending on the selected configuration mode, data must be written to the specified registers as follows:

There are three possibilities:

- 8-bit right justified: software must load data into DAC_DHR8Rx[7:0] bits (store into DHRx[11:4] bits)
- 12-bit left justified: software must load data into DAC_DHR12Lx[15:4] bits (store into DHRx[11:0] bits)
- 12-bit right justified: software must load data into DAC_DHR12Rx[11:0] bits (store into DHRx[11:0] bits)

According to the loaded DAC_DHRyyx register, the data written by the user will be shifted and stored into the corresponding DHRx (Data Holding Register x, which is an internal non-memory-mapped register). After that, the DHRx register will be loaded automatically, or loaded to the DORx register triggered by software or external event.

31	24	15	7	0
				8 bit right justified
				12 bit left justified
				12 bit right justified

28.2.6.2 DAC conversion

DAC_DORx cannot be written directly, any data must be transferred to DAC channel x by loading the DAC_DHRx register (write to DAC_DHR8Rx, DAC_DHR12Lx, DAC_DHR12Rx).

If triggering is not selected (TENx bit reset in DAC_CR register), then the data stored in the DAC_DHRx register is automatically transferred to the DAC_DORx register after one APB1 clock cycle. However, if the hardware trigger is selected (set the TENx bit in the DAC_CR register) and the trigger condition comes, the transfer will take place after three PCLK1 clock cycles.

When DAC_DORx is loaded with DAC_DHRx content, the analog output voltage will be available after a period of tSETTLING depending on supply voltage and analog output load.

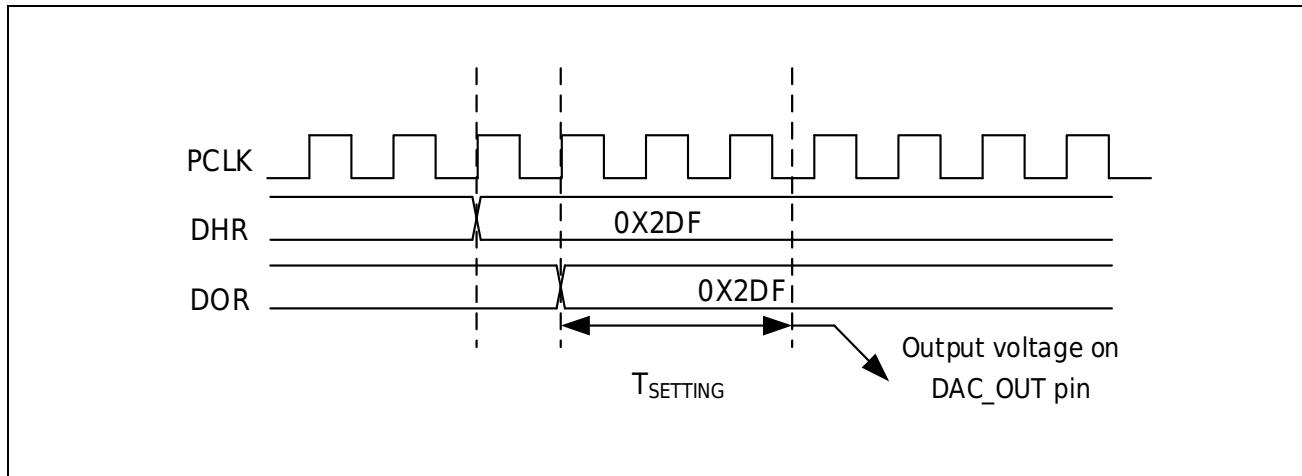

Figure 28-1 Timing diagram of DAC conversion when trigger is disabled

Generate independent triggers for a single LFSR (Linear Feedback Shift Register)

To configure the DAC for this conversion mode (see Noise generation), the following sequence needs to be followed:

1. Set the DAC channel trigger enable bit TENx to 1.
2. Configure the trigger source by setting the TSELx[2:0] bits.
3. Configure the WAVEx[1:0] bits of the DAC channel to "01" and configure the same LFSR mask value in the MAMPx[3:0] bits
4. Load the DAC channel data into the desired DAC_DHRx register (DHR12RD, DHR12LD or DHR8RD).

When the DAC channel x trigger arrives, the LFSRx counter content (using the same mask) is added to the DHRx register content and the sum is transferred into DAC_DORx (after three APB clock cycles). LFSRx counters are then updated.

Generate independent triggers for a single triangle wave

To configure the DAC for this conversion mode (see Triangle wave generation), the following sequence needs to be followed:

1. Set DAC channel x trigger enable bit TENx to 1.
2. Configure the trigger source by setting the TSELx[2:0] bits.
3. Configure the WAVEx[1:0] bits of DAC channel x to "1x" and configure the same maximum

amplitude value in MAMPx[3:0] bits

4. Load the DAC channel x data into the desired DAC_DHRx register (DHR12RD, DHR12LD or DHR8RD).

When the DAC channel x trigger signal arrives, the DAC channel x triangle wave counter content (using the same triangle wave amplitude) is added to the DHRx register content and the resulting sum is transferred into DAC_DORx (after three APB clock cycles). The DAC channel x triangle wave counter is then updated.

28.2.7 Dual mode function description

28.2.7.1 DAC data format

In DAC dual channel mode, there are three possible ways:

- 8-bit right alignment: load the data of DAC0 channel to DAC_DHR8RD[7:0] bits (stored in DHR0[11:4] bits), load the data of DAC1 channel into DAC_DHR8RD[15:8] bits (stored in DHR1[11:4] bits)
- 12-bit left alignment: load the data of DAC0 channel to DAC_DHR12RD [15:4] bits (stored to DHR0[11:0] bits), load the data of DAC1 channel to DAC_DHR12RD [31:20] bits (stored to DHR1[11:0] bits)
- 12-bit right alignment: load the data of DAC0 channel to DAC_DHR12RD [11:0] bits (stored to DHR0[11:0] bits), load the data of DAC1 channel to DAC_DHR12RD [27:16] bits (stored to DHR1[11:0] bits)

Data written by the user will be shifted and stored into DHR0 and DHR1 (data holding registers, internal non-memory-mapped registers) according to the loaded DAC_DHRyyyD register. Afterwards, the DHR0 and DHR1 registers will be loaded automatically, or triggered by software or external events into the DOR0 and DOR1 registers respectively.

28.2.7.2 DAC conversion

The DAC channel conversion in dual mode is performed basically the same as in single mode, the data must be loaded by writing to DAC_DHR8Rx, DAC_DHR12Lx, DAC_DHR12Rx, DAC_DHR8RD, DAC_DHR12LD, or DAC_DHR12RD.

28.2.7.3 DAC Double Conversion Mode Description

To efficiently utilize the bus bandwidth in applications requiring two DAC channels simultaneously, the DAC module has three dual registers available for operation: DHR8RD, DHR12RD, and DHR12LD. This allows two DAC channels to be driven simultaneously with only one register access.

Eleven conversion modes are possible through two DAC channels and these three dual registers. But all of these conversion modes can also be implemented through separate DHRx registers if required.

All of these modes are described in the following paragraphs.

Independent triggering (does not generate waveforms)

To configure the DAC for this conversion mode, the following sequence needs to be followed:

1. Set the two DAC channel trigger enable bits TEN0 and TEN1 to 1
2. Set TSEL1[2:0] and TSEL0[2:0] to different values to configure different trigger sources
3. Load DAC dual channel data into desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD)

When the DAC0 channel trigger signal arrives, the content of the DHR0 register is transferred to DAC_DOR0 (after three APB clock cycles).

When the DAC 1 channel trigger signal arrives, the content of the DHR1 register is transferred to DAC_DOR1 (after three APB clock cycles).

Trigger independently (generates a single LFSR)

To configure the DAC for this conversion mode (see Noise generation), the following sequence needs to be followed:

1. Set the two DAC channel trigger enable bits TEN1 and TEN0 to 1
2. Set TSEL1[2:0] and TSEL0[2:0] to different values to configure different trigger sources
3. WAVE_x[1:0] of both DAC channels to "01" and configure the same LFSR mask value in MAMP_x[3:0] bits
4. Load DAC dual channel data into desired DHR register (DHR12RD, DHR12LD or DHR8RD)

When the DAC channel 0 trigger signal arrives, the LFSR0 counter content (using the same mask) is added to the DHR0 register content and the resulting sum is transferred into DAC_DOR0 (after three APB clock cycles). LFSR0 counter is then updated.

When the DAC channel 1 trigger signal arrives, the LFSR1 counter content (using the same mask) is added to the DHR1 register content and the resulting sum is transferred into DAC_DOR1 (after three APB clock cycles). The LFSR1 counter is then updated.

Trigger independently (generate different LFSRs)

To configure the DAC for this conversion mode (see Noise generation), the following sequence needs to be followed:

1. Set the two DAC channel trigger enable bits TEN1 and TEN0 to 1
2. Set TSEL1[2:0] and TSEL0[2:0] to different values to configure different trigger sources
3. Set WAVE_x[1:0] to "01" for both DAC channels and set different LFSR mask values in

MAMP1[3:0] and MAMPO[3:0] bits

4. Load DAC dual channel data into desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD)

When the DAC channel 0 trigger signal arrives, the LFSR0 counter content (mask configured using MAMPO[3:0]) is added to the DHR0 register content and the resulting sum is transferred into DAC_DOR0 (after three APB clock cycles). LFSR0 counter is then updated.

When the DAC channel 1 trigger signal arrives, the LFSR1 counter content (mask configured using MAMP1[3:0]) is added to the DHR1 register content and the resulting sum is transferred into DAC_DOR1 (after three APB clock cycles). The LFSR1 counter is then updated.

Independent triggering (generates a single triangle wave)

To configure the DAC for this conversion mode (see Triangle wave generation), the following sequence needs to be followed:

1. Set DAC channel x trigger enable bit TENx to 1.
2. Configure different trigger sources by setting different values in TSELx [2:0] bits
3. Configure the WAVE[1:0] bits of DAC channel x to "1x" and configure the same maximum amplitude value in MAMPx[3:0] bits
4. Load DAC channel x data into desired DAC_DHRx register

See Section 15.5.2: DAC Channel Conversions for details on which AHB bus (APB or APB1) to clock the DAC conversions.

When the DAC channel x trigger signal arrives, the DAC channel x triangle wave counter content (using the same triangle wave amplitude) is added to the DHRx register content and the resulting sum is transferred into DAC_DORx (after three APB clock cycles). The DAC channel x triangle wave counter is then updated.

Independent triggering (generation of different triangle waves)

To configure the DAC for this conversion mode (see Triangle wave generation), the following sequence needs to be followed:

1. Set DAC channel x trigger enable bit TENx to 1.
2. Configure different trigger sources by setting different values in TSELx [2:0] bits
3. Set the WAVE[1:0] bits of the DAC channel x to "1x" and set a different maximum amplitude value in the MAMPx[3:0] bits
4. Load DAC channel x data into desired DAC_DHRx register

When the DAC channel x trigger signal arrives, the DAC channel x triangle wave counter content (triangle wave amplitude configured using MAMPx[3:0]) is added to the DHRx register content, and the resulting sum is transferred to DAC_DORx (after three APB clock cycles). The DAC channel x triangle wave counter is then updated.

Synchronization software starts

To configure the DAC for this conversion mode, the following sequence needs to be followed:

1. Load DAC dual channel data into desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD)

This configuration uses one APB clock cycle.

Synchronous triggering (does not generate waveforms)

To configure the DAC for this conversion mode, the following sequence needs to be followed:

1. Set the two DAC channel trigger enable bits TEN1 and TEN0 to 1
2. Set TSEL1[2:0] and TSEL0[2:0] to the same value to configure the same trigger source for both DAC channels
3. Load DAC dual channel data into desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD)

When the trigger signal arrives, the DHR1 and DHR0 register contents will be transferred to DAC_DOR1 and DAC_DOR0 respectively (after three APB clock cycles).

Synchronous triggering (generates a single LFSR)

To configure the DAC for this conversion mode (see Noise generation), the following sequence needs to be followed:

1. Set the two DAC channel trigger enable bits TEN1 and TEN0 to 1
2. Set TSEL1[2:0] and TSEL2[2:0] to the same value to configure the same trigger source for both DAC channels
3. WAVE_x[1:0] of both DAC channels to "01" and configure the same LFSR mask value in MAMP_x[3:0] bits
4. Load the DAC dual channel data into the desired DHR register (DHR12RD, DHR12LD or DHR8RD) When the trigger signal arrives, the LFSR1 counter content (using the same mask) is added to the DHR1 register content and the resulting sum is transferred to DAC_DOR1 (three APB clock cycle later). The LFSR1 counter is then updated. At the same time, the LFSR0 counter content (using the same mask) is added to the DHR0 register content, and the resulting sum is transferred into DAC_DOR0 (after three APB clock cycles). LFSR0 counter is then updated.

Synchronous triggering (generating different LFSRs)

To configure the DAC for this conversion mode (see Noise generation), the following sequence needs to be followed:

1. Set the two DAC channel trigger enable bits TEN1 and TEN0 to 1
2. Set TSEL1[2:0] and TSEL0[2:0] to the same value to configure the same trigger source for both DAC channels

3. WAVE x [1:0] of both DAC channels to "01" and set different LFSR mask values in MAMP1[3:0] and MAMP2[3:0] bits
4. Load the DAC dual channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD) When the trigger signal arrives, the LFSR1 counter content (mask configured using MAMP1[3:0]) is added to the DHR1 register content and the resulting sum is transferred to DAC_DOR1 (after three APB clock cycles). The LFSR1 counter is then updated.

At the same time, the LFSR0 counter content (mask configured using MAMP0[3:0]) is added to the DHR0 register content and the resulting sum is transferred into DAC_DOR0 (after three APB clock cycles). LFSR0 counter is then updated.

Synchronous triggering (generates a single triangle wave)

To configure the DAC for this conversion mode (see Triangle wave generation), the following sequence needs to be followed:

1. Set DAC channel x trigger enable bit TEN1 x to 1.
2. Set the same value in the TSEL x [2:0] bits to configure the same trigger source for both DAC channels.
3. Configure the WAVE x [1:0] bits of DAC channel x to "1x" and use the MAMP x [3:0] bits to configure the same maximum amplitude value
4. Load DAC channel x data into desired DAC_DHR x register.

When the trigger signal arrives, the DAC channel x triangle wave counter content (using the same triangle wave amplitude) is added to the DHR x register content and the resulting sum is transferred into DAC_DOR x (after three APB clock cycles). The DAC channel x triangle wave counter is then updated.

Synchronous trigger (generate different triangle waves)

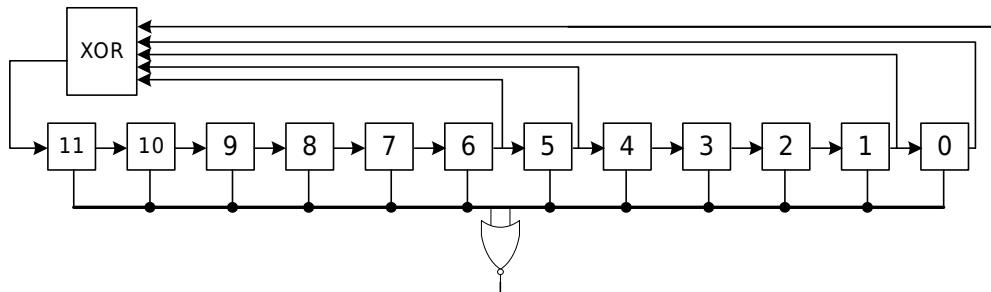

To configure the DAC for this conversion mode (see Triangle wave generation), the following sequence needs to be followed:

1. Set DAC channel x trigger enable bit TEN x to 1.
2. Set the same value in the TSEL x [2:0] bits to configure the same trigger source for DAC channel x.
3. Configure the WAVE x [1:0] bits of the DAC channel x as "1x" and set a different maximum amplitude value in the MAMP x [3:0] bits.
4. Load DAC channel x data into desired DAC_DHR x register.

When the trigger signal arrives, the DAC channel x triangle wave counter content (triangle wave amplitude configured using MAMP x [3:0]) is added to the DHR x register content, and the resulting sum is transferred into DAC_DOR x (after three APB clock cycles). The DAC channel x triangle wave counter is then updated.

28.2.8 Noise generation

To generate pseudo noise of variable amplitude, LFSRs (Linear Feedback Shift Registers) are used. Set WAVE_x[1:0] to "01" to choose to generate noise. The preload value in LFSR is 0xAAA. After each trigger event, after three APB clock cycles, the register will be updated according to a specific calculation algorithm.

The LFSR value can be partially or completely masked by the MAMP_x[3:0] bits in the DAC_CR register. In the case of no overflow, the value will be added to the content of DAC_DHR_x and then stored in the DAC_DOR_x register.

If LFSR is 0x0000, "1" will be injected into it (anti-lock mechanism).

The LFSR waveform generation function can be disabled by resetting the WAVE_x[1:0] bits.

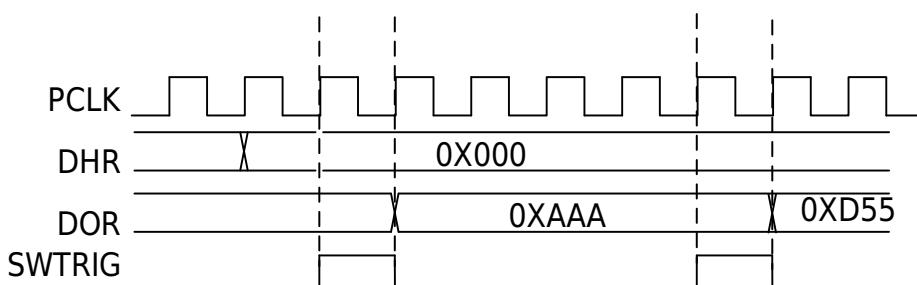

Figure 28-2 DAC conversion of waveform generated by LFSR (using software trigger)

28.2.9 Triangle wave generation

A small-amplitude triangle wave can be superimposed on a DC current or slowly varying signal. Set WAVE_x[1:0] to "10" to select DAC to generate triangle wave. The amplitude is configured by the MAMP_x[3:0] bits in the DAC_CR register. After each trigger event, after three APB clock cycles, the internal triangle wave counter will be incremented. In case overflow does not occur, the value of this counter is added to the contents of the DAC_DHR_x register and the sum is stored in the DAC_DOR_x register. As long as it is less than the maximum amplitude defined by the MAMP_x[3:0]

bits, the triangle wave counter will keep incrementing. Once the configured amplitude is reached, the counter is decremented to zero, then incremented, and so on.

The triangle wave generation function can be turned off by resetting the WAVE[1:0] bits.

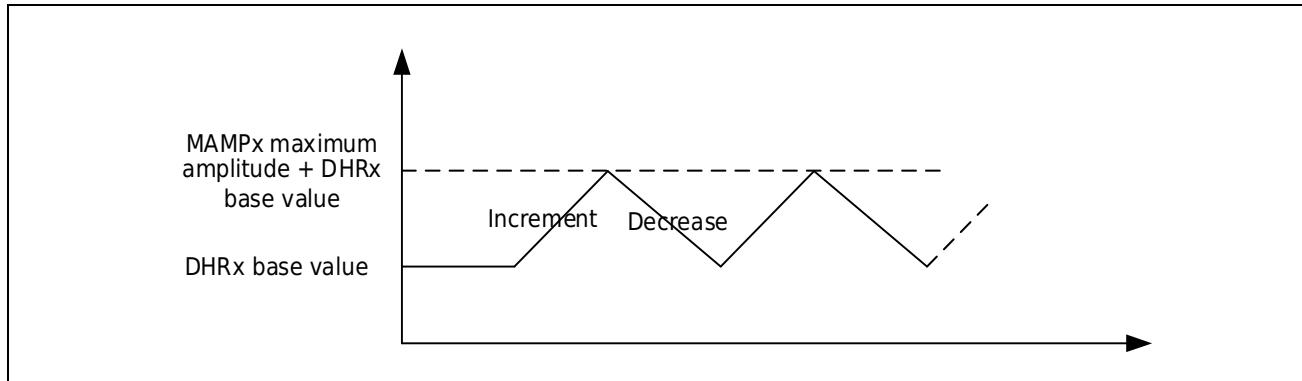

Figure 28-3 Generate DAC triangle wave

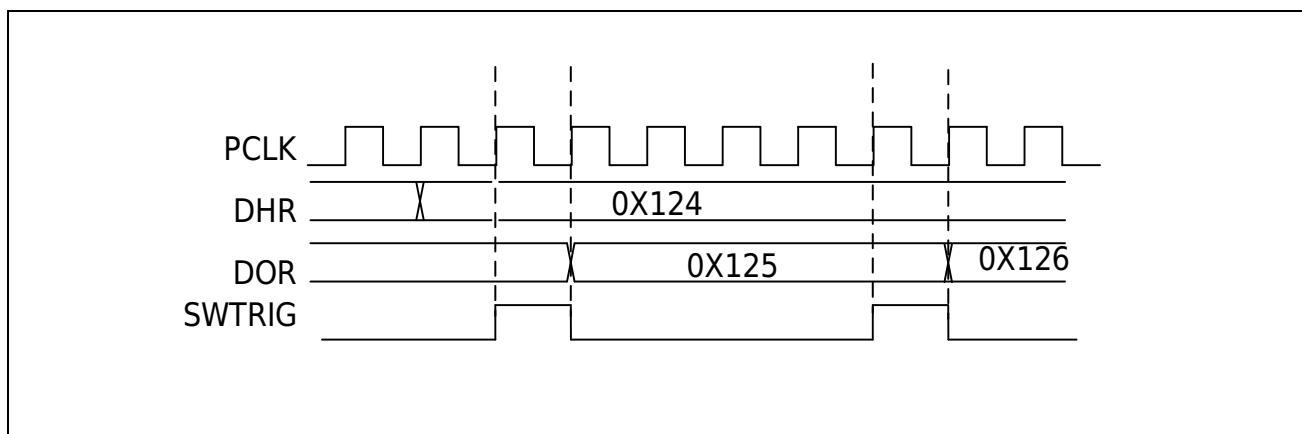

Figure 28-4 DAC conversion to generate triangle waveform (software trigger enabled)

28.2.10 DMA request

Each DAC channel has DMA capability. Two DMA channels are used to handle DMA requests from the DAC channel.

When the DMAENx bit is set, a DAC DMA request will be generated if a trigger occurs. DAC_DHRx register is then transferred to the DAC_DORx register.

In dual channel mode, if both DMAENx bits are set, two DMA requests will be generated. The user should only set the corresponding DMAENx bit if only one DMA request is required. This way the application can manage two DAC channels in dual channel mode with one DMA request and one specific DMA channel.

DMA underflow

There is no buffer queue for DAC DMA requests. In this way, if the acknowledgment of the first external trigger has not been received when the second external trigger arrives, no new request

will be issued and the DAM channel underflow flag DMAUDRx in the DAC_SR register will be set to 1 to report this error condition. DMA data transfers are then disabled and no other DMA requests are processed. DAC channel will still continue to convert legacy data.

DMAUDRx flag by writing '0', clear the DMAEN bit for the DMA data stream being used, and reinitialize the DMA and DAC channels to properly restart the DMA transfer. Software should modify the frequency of DAC trigger conversions or reduce the DMA workload to avoid DMA underflow from happening again. DAC conversions can be continued by enabling DMA data transfers and conversion triggers.

For each DAC channel, an interrupt will also be generated if the corresponding DMAUDRIEx bit in the DAC_CR register is enabled.

29 Analog Comparator (VC)

29.1 Introduction to Analog Voltage Comparator VC

The analog voltage comparator VC is used to compare the size of two input analog voltages, and output high / low level according to the comparison result. When the "+" input voltage is higher than the "-" input voltage, the voltage comparator output is high; when the "+" input voltage is lower than the "-" input voltage, the voltage comparator output is low flat. The analog voltage comparator VC integrated in this product has the following characteristics:

- Support voltage comparison function;
- Support internal 64- stage VCC voltage divider (use the voltage divider source voltage to be greater than 1.8V);
- Support 16 external input ports as the input of the voltage comparator;
- Support three software-configurable interrupt trigger modes: high level trigger / rising edge trigger / falling edge trigger;
- The output of the voltage comparator can be used as General purpose timer and Low-power timer control input;
- The output of the voltage comparator can be used as Brake input or capture input for advanced timers and general-purpose timers;
- Support working in ultra-low power consumption mode, the interrupt output of the voltage comparator can wake up the chip from ultra-low power consumption mode;
- Provide software configurable filter time to enhance the anti-interference ability of the chip.

Note: BGR needs to be enabled when using VC, refer to BGR register description.

29.2 Voltage Comparator Block Diagram

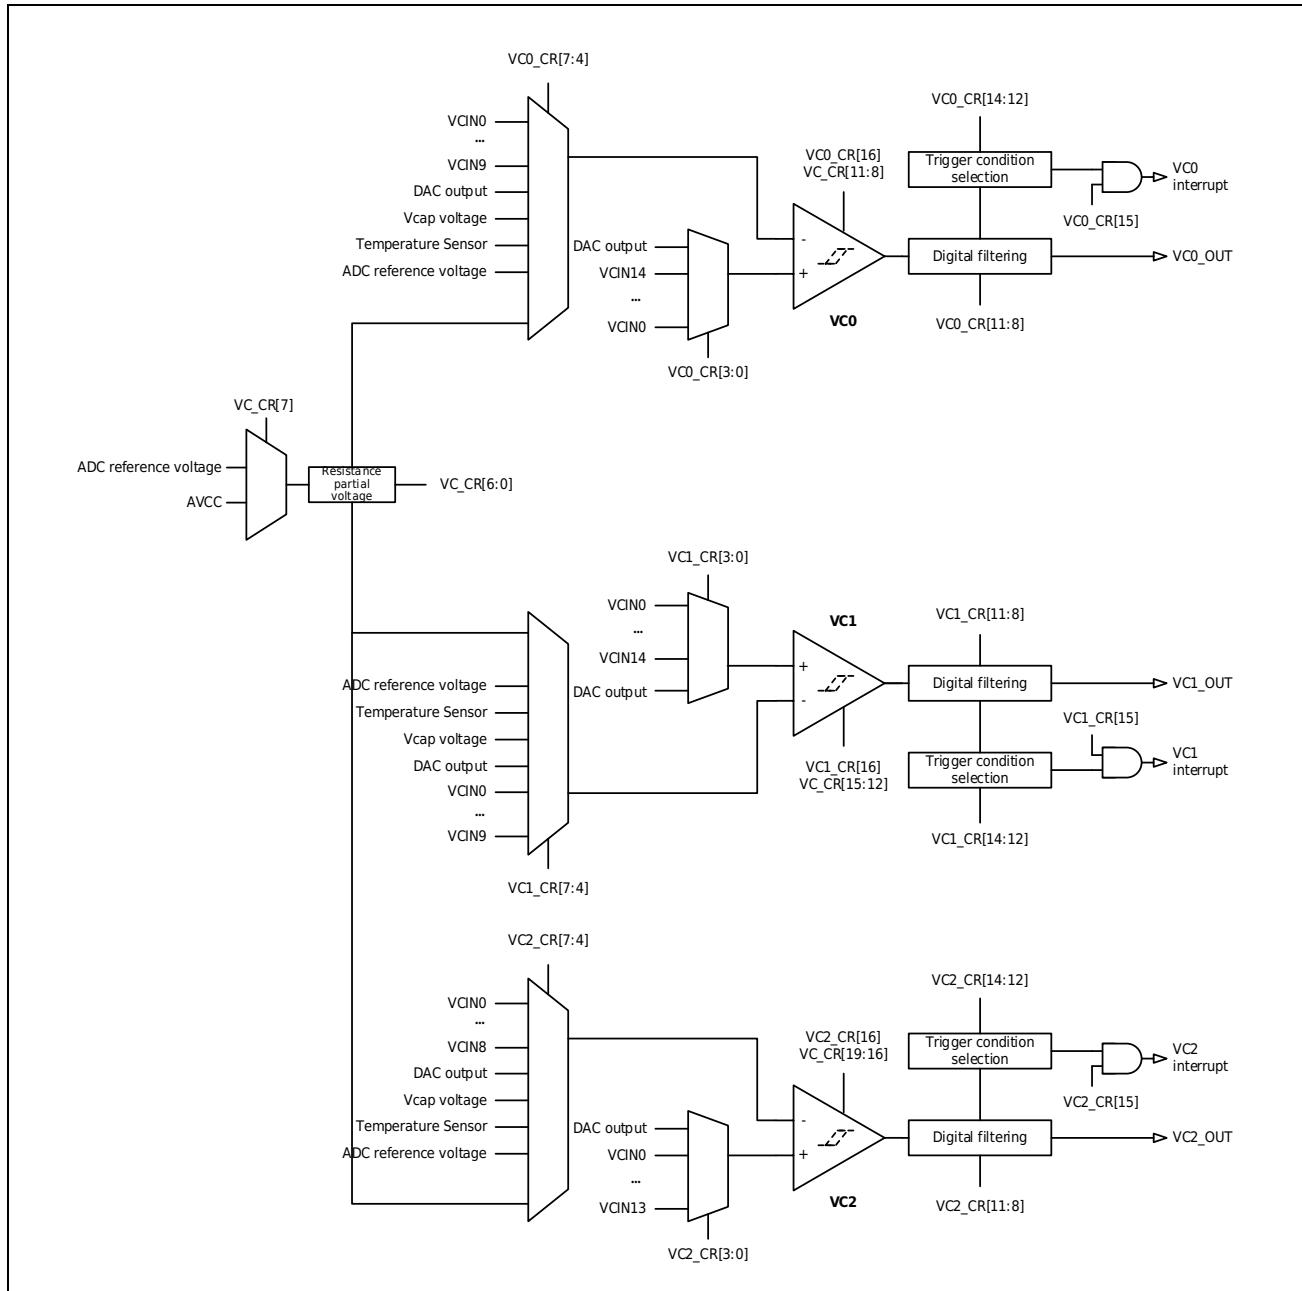

Figure 29-1 VC Frame Diagram

29.3 Setup / Response Time

When using a voltage comparator, the time from when VC is enabled or when the input voltage at both ends of VC changes to when the correct result is output is determined by the BIAS_SEL control bit in the VC control register (VC_CR). The larger the current, the faster the VC response, typical value Four levels are adjustable from 200ns to 20us.

If needed, the internal BGR provides a reference voltage (1.5V or 2.5V) as a comparison reference voltage. The start-up time of the internal BGR is about 20us, and the voltage comparator needs to wait for the internal BGR to stabilize before outputting normally.

29.4 Filter time

In addition to the inherent settling/response time of the voltage comparator, the user can set a longer filter time to filter out system noise, such as high current noise when the motor stops.

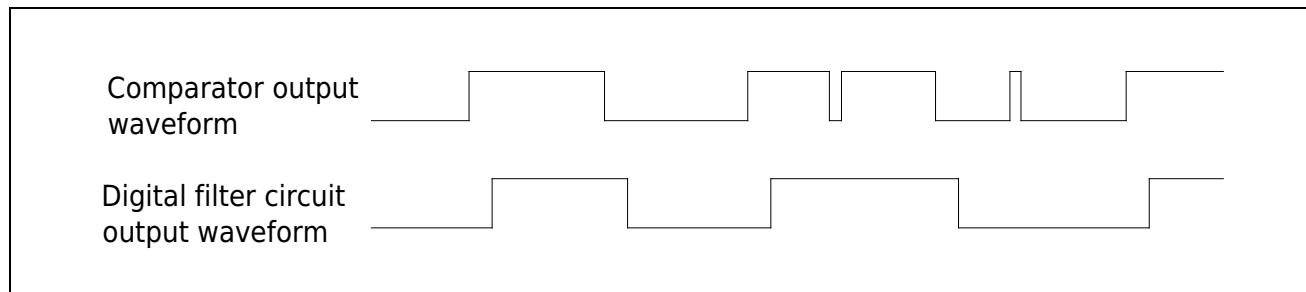

Figure 29-2 VC Filter Response Time

29.5 Hysteresis function

The hysteresis function can be selected for the voltage comparator, and the diagram after the hysteresis function is enabled is as follows:

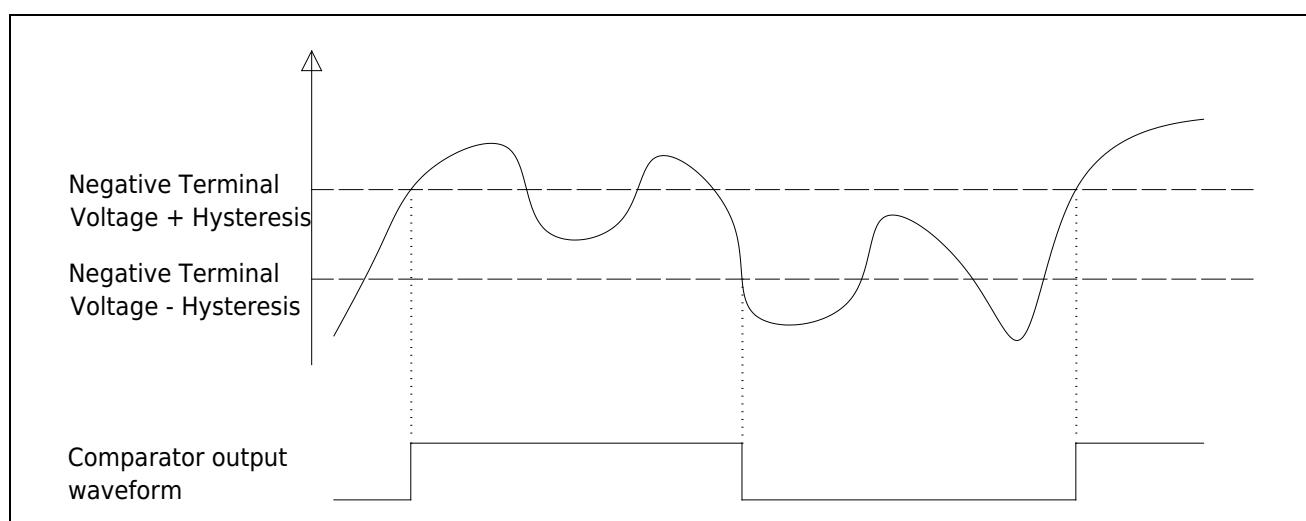

Figure 29-3 VC hysteresis function

30 Low Voltage Detector (LVD)

30.1 Introduction to LVD

LVD can be used to monitor the voltage of VCC and chip pins. When the comparison result of the monitored voltage and the LVD threshold meets the trigger condition, the LVD will generate an interrupt or reset signal, and the user can perform some urgent tasks according to the signal.

LVD has the following characteristics:

- 4 -channel monitoring sources, AVCC, PC13, PB08, PB07;
- 16-step threshold voltage, 1.8V~3.3V optional;
- 8 trigger conditions, combinations of high level, rising edge and falling edge;
- 2 trigger results, reset and interrupt;
- 8-stage filter configuration to prevent false triggering;
- With hysteresis function, strong anti-interference.

30.2 LVD block diagram

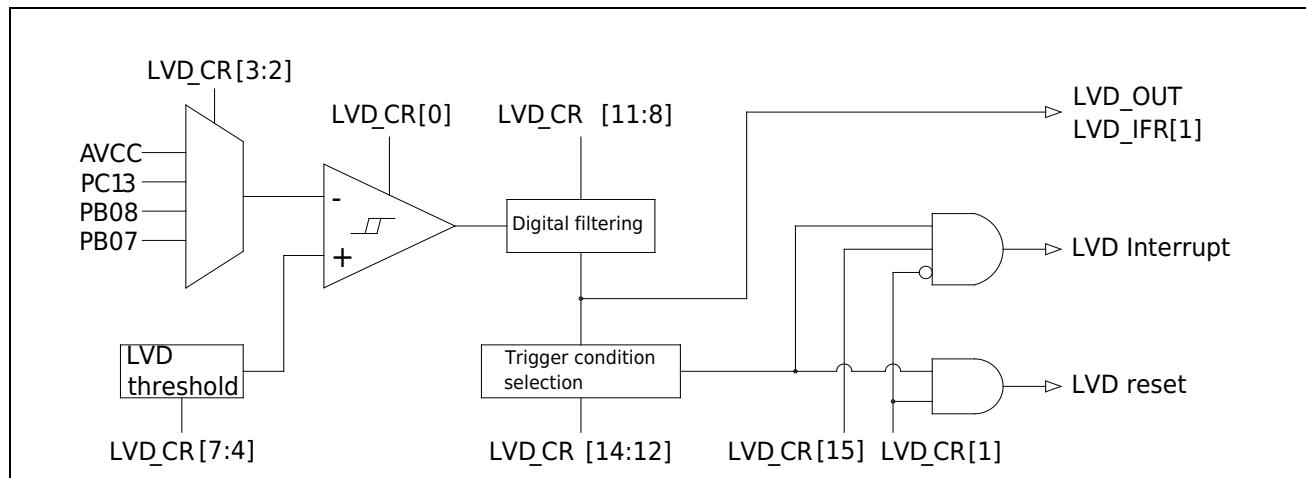

Figure 30-1 LVD Block Diagram

30.3 Hysteresis function

The built-in voltage comparator of LVD has a hysteresis function, which can enhance the anti-interference ability of the chip. LVD will not flip until the input signal is higher or lower than the threshold voltage of 20mV. The input and output signals are as follows:

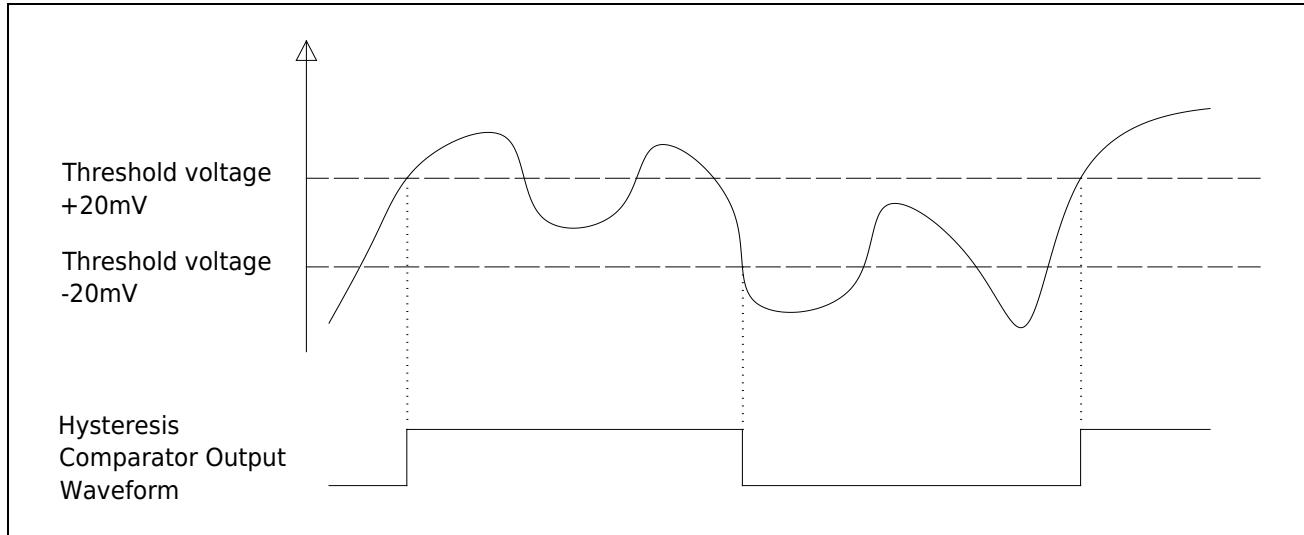

Figure 30-2 LVD hysteresis response

30.4 Digital filtering

If the working environment of the chip is bad, the output of the hysteresis comparator will appear noise signal. When the digital filtering module is enabled, the noise signal whose pulse width is less than LVD_CR.Debounce_time in the output waveform of the hysteresis comparator can be filtered out. If the digital filter module is disabled, the input and output signals of the digital filter module are the same.

The digitally filtered signal level can be read from the register LVD_IFR[1]; when the GPIO function is configured as LVD_OUT the digitally filtered signal can be output from the GPIO for easy measurement.

Enable the digital filtering module, and the filtering diagram is as follows:

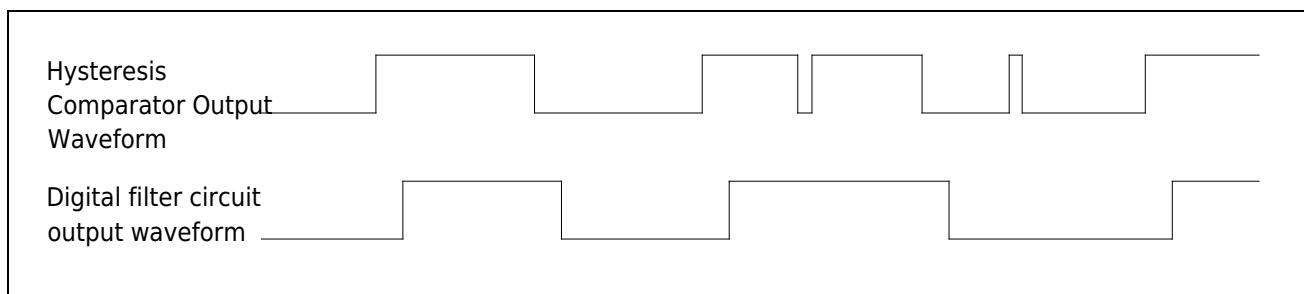

Figure 30-3 LVD filter output

30.5 Configuration example

30.5.1 LVD configured as low voltage reset

In this mode, the MCU is reset when the monitored voltage is lower than the threshold voltage.

The configuration method is as follows:

Step1: Configure LVD_CR.Source_sel to select the voltage source to be monitored.

Step2: Configure LVD_CR. VTDS, select the threshold voltage of LVD.

Step3: Configure LVD_CR. Debounce_time, select LVD filter time.

Step4: Configure LVD_CR. FLTEN to enable LVD filtering.

Step5: Set LVD_CR. HTEN to 1, select high level to trigger LVD action.

Step6: Set LVD_CR.ACT to 1, select LVD action as reset.

Step7: Set LVD_CR.LVDEN to 1 to enable LVD.

30.5.2 LVD configured as voltage change interrupt

In this mode, an interrupt is generated when the monitored voltage goes above or below the threshold voltage.

The configuration method is as follows:

Step1: Configure LVD_CR.Source_sel to select the voltage source to be monitored.

Step2: Configure LVD_CR. VTDS, select the threshold voltage of LVD.

Step3: Configure LVD_CR. Debounce_time, select LVD filter time.

Step4: Configure LVD_CR. FLTEN to enable LVD filtering.

Step5: Set LVD_CR. RTEN and LVD_CR. FTEN to 1, select level change to trigger LVD action.

Step6: Set LVD_CR.ACT to 0, select LVD action as interrupt.

Step7: Set LVD_CR.IE to 1 to enable LVD interrupt.

Step8: Enable the LVD interrupt in the NVIC interrupt vector table.

Step9: Set LVD_CR.LVDEN to 1 to enable LVD.

Step10: Execute the operations required by the user in the LVD interrupt service routine; write 0x00 to LVD_IFR to clear the interrupt flag before exiting the interrupt service routine.

31 Operational Amplifier (OPA)

The OPA module is suitable for simple amplifier and voltage follower applications. The five internal op amps can be cascaded using external resistors. The input range of OPA is 0V to AVCC, and the output range is 0.1V to AVCC-0.2V.

31.1 OPA features

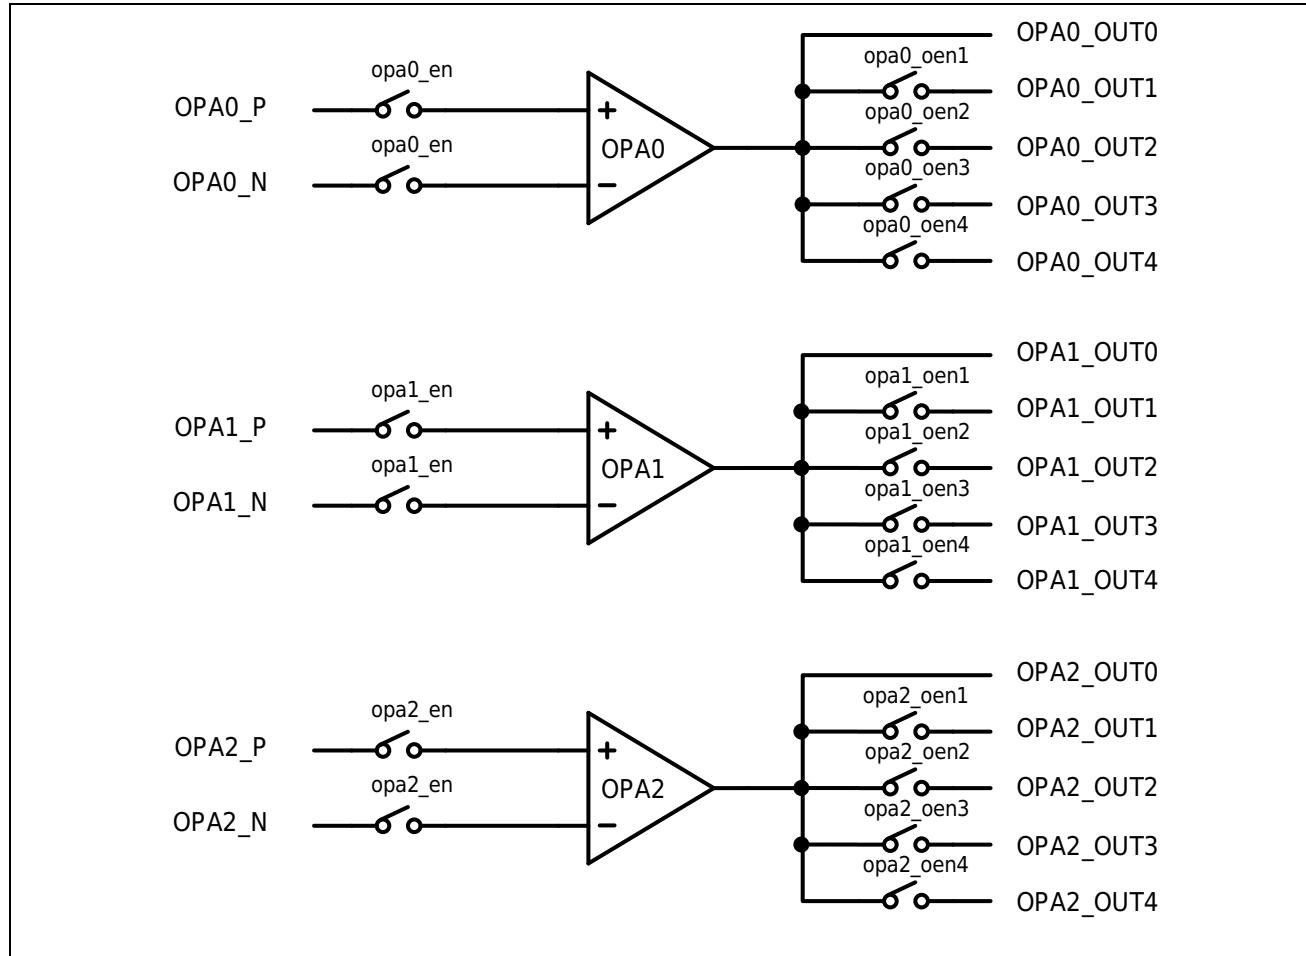

- 5 independently configured op amps
- OPA input range is 0 to AVCC, output range is 0.1V to AVCC-0.2V programmable gain
- Can be configured in the following modes
 - Universal op amp mode (general purpose OPA)
 - DAC voltage follower

31.2 OPA Functional Description

5 OPAs can amplify small-signal analog input signals by using external components to form an amplifier, and output the amplified signal.

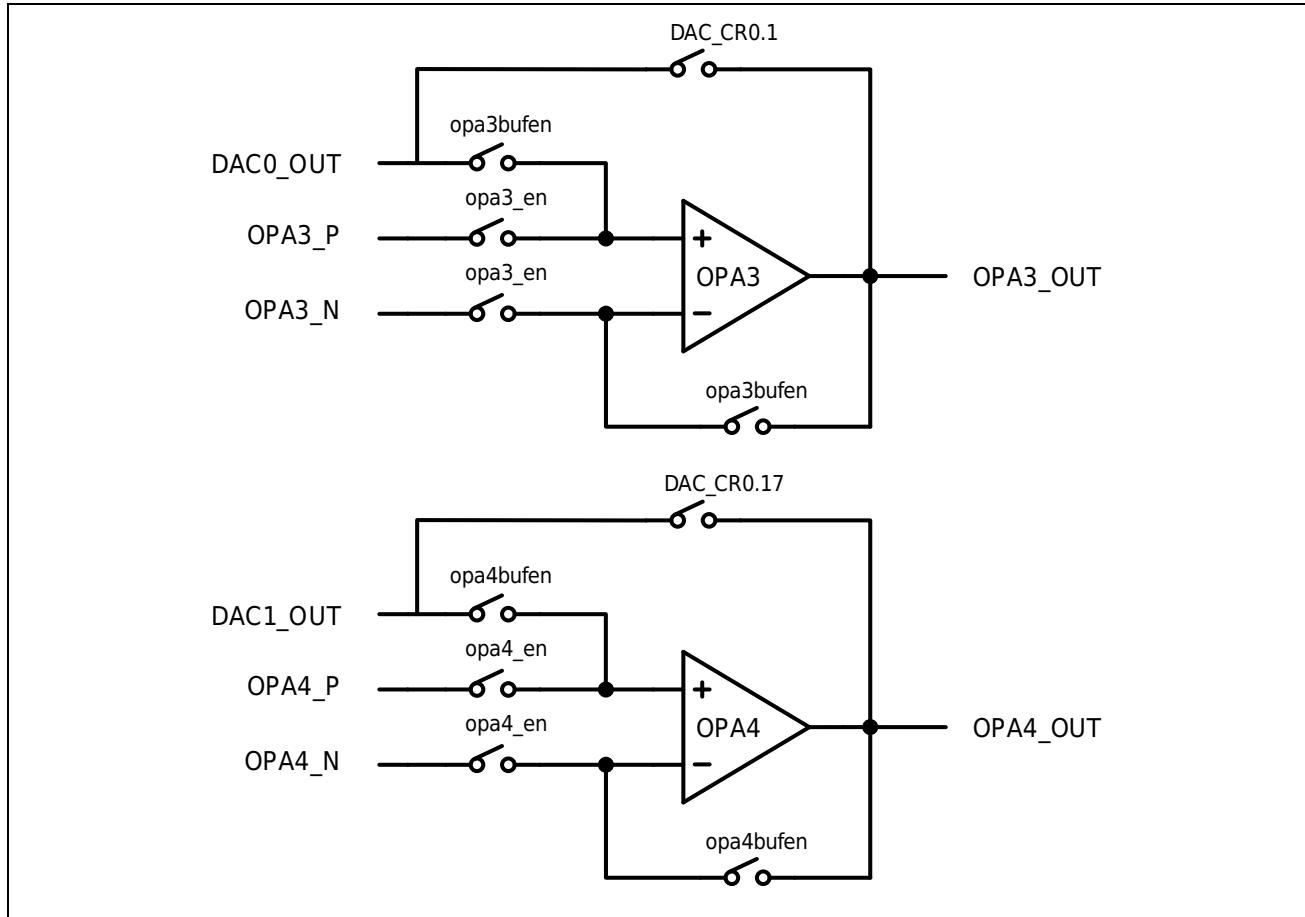

31.2.1 OPA0/1/2 (Generic OPA)

OPA0/1/2 is as follows:

31.2.2 OPA3/4 --- (can be multiplexed as DAC buffer*2)

OPA3/4 is as follows:

31.3 OPA zero calibration

OPA supports automatic zero calibration in different modes, which can be controlled by software or hardware. For high-precision OPA applications, OPA zero calibration is required before each use of OPA. The recommended time for zero calibration is more than 10us. Sample immediately after zero calibration.

31.3.1 Software control

- Enable the OPA_CRx.AZEN of the OPA that needs zero calibration to be 1
- Set OPA_CR.CLK_SW_SET to 1
- The software writes OPA_CR.AZ_PULSE is 1
- Set the zero calibration time, wait for the zero calibration time to end, clear OPA_CR.AZ_PULSE is 0

31.3.2 Software trigger control

- Enable the OPA_CRx.AZEN of the OPA that needs zero calibration to be 1
- OPA_CR.CLK_SEL that needs to be zeroed
- Set software trigger OPA_CR.TRIGGER

31.3.3 ADC trigger control

- Enable the OPA_CRx.AZEN of the OPA that needs zero calibration to be 1
- OPA_CR.CLK_SEL that needs to be zeroed
- Enable ADC trigger ADCTR_EN

31:2	Reserved	Keep
1	TS_EN	Built-in temperature sensor enable control 1: Enable internal temperature sensor 0: disable internal temperature sensor Note: After the temperature sensor is enabled for 20us, it can output a stable signal.
0	BGR_EN	BGR enable control 1: enable BGR 0: disable BGR Note: 1) This register can only be operated when Peri_clken0.ADC is 1. 2) After BGR is enabled for 20us, a stable high-precision reference voltage can be output. After the BGR is stable, it can be used by other modules, so the steps of waiting for the BGR to be stable should be added in the user operation. 3) When using ADC/OPA/PLL, BGR must be enabled. 4) When using VC, it is necessary to decide whether to enable BGR according to the configuration of the VC register.

33 SWD debug interface

This series uses the ARM Cortex-M0+ core, which has a hardware debug module SWD that supports complex debugging operations. The hardware debug module allows the core to stop when fetching instructions (instruction breakpoints) or accessing data (data breakpoints). When the kernel is stopped, both the internal state of the kernel and the external state of the system can be queried in the IDE. After the query is complete, the core and peripherals can be restored and program execution continues. When this series of microcontrollers are connected to a debugger and start debugging, the debugger will use the kernel's hardware debugging module to perform debugging operations.

Note:

- SWD can't work in DeepSleep mode, please debug in Active and Sleep mode.

33.1 SWD debugging additional functions

This product uses the ARM Cortex-M0+ CPU, which includes hardware extensions for advanced debugging functions, so this product has the same debugging functions as Cortex-M0+. Debug extensions allow the kernel to halt the kernel when fetching instructions (instruction breakpoints) or fetching data (data breakpoints). When the kernel stops, you can query the internal state of the kernel and the external state of the system. After the query completes, the kernel and system are restored and program execution is restored.

When the debug host is connected to the MCU and debugged, the debug function will be used.

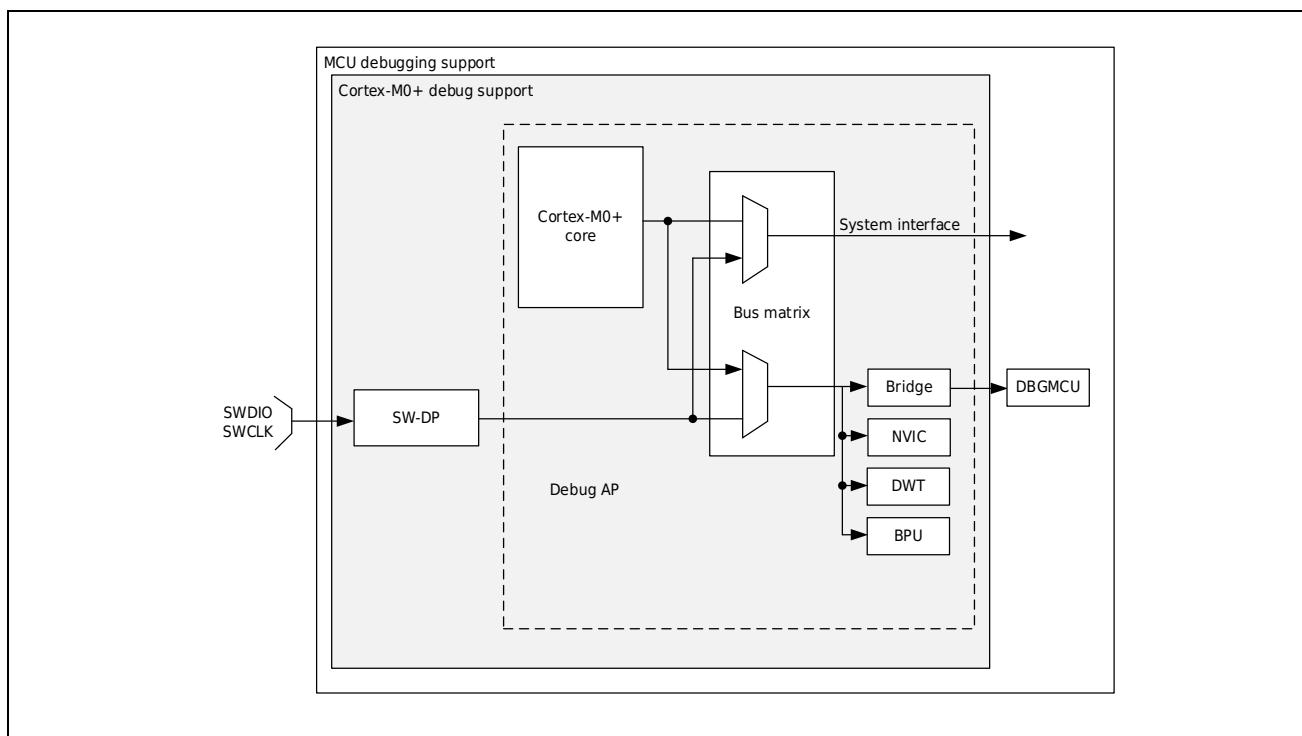

Figure 33-1 Debug Support Block Diagram

Debug features built into the Cortex®-M0+ core are part of the ARM® CoreSight Design Suite.

The ARM® Cortex®-M0+ core provides integrated on-chip debugging support. It includes:

- SW-DP: serial line
- BPU: Breakpoint unit
- DWT: data watchpoint trigger

Note:

- Details on the debug features supported by the ARM® Cortex®-M0+ core can be found in the Cortex® -M0+ Technical Reference Manual.

33.2 ARM® Reference Documentation

- Cortex®-M0+ Technical Reference Manual (TRM)

Available from www.infocenter.arm.com.

- ARM® Debug Interface V5
- ARM® CoreSight Design Suite Version r1p1 Technical Reference Manual

33.3 Debug port pins

33.3.1 SWD port pin

The SWD interface of this series requires 2 pins, as shown in the table below.

SWD port name	Debug function	Pin assignment
SWCLK	Serial clock	PA14
SWDIO	Serial data input / output	PA13

33.3.2 SW-DP pin assignment

If the [Encryption Chip] option is enabled when programming the program, the SWD debugging function will be disabled after power-on. If the [encrypted chip] option is not enabled when programming the program, the PA13/PA14 pins are initialized as dedicated pins that can be used by the debugger after power-on. Users can set the SYSCtrl1.SWD_USE_IO register to disable the SWD pin debug function, and the SWD pin will be released to be used as a normal GPIO. SWD pins are summarized in the following table:

[Encryption chip] option	SWD_USE_IO configuration	PA13/PA14 function
Encryption	0	NA
Encryption	1	GPIO
No encryption	0	SWD
No encryption	1	GPIO

33.3.3 Internal pull-up on SWD pin

After the user software releases the SW I/O, the GPIO controller takes control of these pins. GPIO control register puts the I/O into the equivalent state:

- SWDIO: input pull-up
- SWCLK: input pull-up

No external resistors need to be added due to built-in pull-up and pull-down resistors.

33.4 SWD port

33.4.1 Introduction to SWD Protocol

This synchronous serial protocol uses two pins:

- SWCLK: Clock from host to target
- SWDIO: Bidirectional

Using this protocol, two register sets (DPACC register set and APACC register set) can be read and written simultaneously. When transferring data, the LSB comes first.

For SWDIO bidirectional management, the line must be pulled up on the board (ARM® recommends 100 k). These pull-up resistors are internally configurable. No external pull-up resistors are required.

Every time the SWDIO direction is changed in the protocol, the conversion time is inserted, and the line is not driven by the host or the target. By default, this conversion time is one bit time, but it can be adjusted by configuring the SWCLK frequency.

33.4.2 SWD protocol sequence

Each sequence consists of three phases:

1. The host sends a packet request (8 bits)
2. Acknowledgment response sent by target (3 digits)
3. The host or target sends the data transfer phase (33 bits)

Bit	Name	Note
0	Start up	Must be 1
1	APnDP	0: DP access; 1: AP access
2	RnW	0: write request; 1: read request
4:3	A[3:2]	Address field of DP or AP register
5	Parity	Unit parity for the first few bits
6	Stop	0
7	Reside	Not driven by the host. 1 by target due to pull-up

For a detailed description of the DPACC and APACC registers, refer to the Cortex®-M0+ TRM.

The packet request is always followed by a conversion time (1 bit by default), at which point neither the host nor the target will drive.

Bit	Name	Note
0	ACK	001: FAULT 010: WAIT 100: OK

The ACK response must be followed by transition time only when a READ transaction occurs or a WAIT or FAULT acknowledgment is received.

Bit	Name	Note
0:31	WDATA or RDATA	Write or Read data
32	Parity	Single parity for 32 data bits

The transfer time must be after the DATA transfer only when a READ transaction occurs.

33.4.3 SW-DP state machine (reset, idle state, ID code)

SW-DP has an internal ID code for identifying SW-DP. The code is JEP-106 compliant. This ID code is the default ARM® code, set to 0x0BB11477 (equivalent to Cortex®-M0+).

Note:

- The SW-DP state machine is inactive until the target reads the ID code.
- The SW-DP state machine is in reset state after power-on reset or after the line has been at high level for more than 50 cycles.
- If the line is low for at least two cycles after the reset state, the SW-DP state machine is in the idle state.
- After the reset state, the state machine must first enter the idle state and then perform a read access to the DP-SW ID CODE register. FAULT acknowledgment response on another transaction.

Cortex®-M0+ TRM and CoreSight Design Suite r1p0TRM for more details on the SW-DP state machine.

33.4.4 DP and AP read / write access

- DP is not delayed: the target response can be sent immediately (if ACK=OK) or delayed (if ACK=WAIT).
- Delay read access to AP. This means that access results will be returned on the next transfer. If the next access to be performed is not an AP access, the DP-RDBUFF register must be read to obtain the result.
- Every time an AP read access or RDBUFF read request is made, the READOK flag of the DP-CTRL/STAT register will be updated to know whether the AP read access is successful.
- SW-DP has a write buffer (for DP or AP writes) so that write operations can be accepted even while other operations are still pending. If the write buffer is full, the target acknowledgment

response is WAIT. Except for IDCODE read, CTRL/STAT read or ABORT write, these operations will also be accepted when the write buffer is full.

- Due to the asynchronous clock domains SWCLK and HCLK, two additional SWCLK cycles are required after the write operation (after the parity bit) for the write operation to take effect internally. These cycles should be applied while the line is being driven low (idle state).

This is especially important when writing to the CTRL/STAT register to initiate a power-on request. Otherwise the next operation (one that is only valid after the core is powered on) will be executed immediately, which will cause a failure.

33.4.5 SW-DP register

These registers can be accessed when APnDP=0:

A[3:2]	RW	CTRLSEL bit of the SELECT register	Register	Note
00	Read		IDCODE	Manufacturer code set to default ARM® for Cortex®-M0+ Code. 0x0BB11477 (identifies SW-DP)
00	Write		ABORT	
01	Read / Write	0	DP-CTRL/STAT	Purpose: - Request system or debug power up - Configure transport operations for AP access - Control compare and verify operations - read some status flags (overflow and power-on acknowledgment)
01	Read / Write	1	WIRE CONTROL	Used to configure the physical serial port protocol (such as switching time duration)
10	Read		READ RESEND	Allow recovery of reads from corrupted debug software transfers data without repeating the original AP transmission.
10	Write		SELECT	4-word register used to select the currently accessed port and active window
11	Read / Write		READ BUFFER	Since the AP access has been issued, this read buffer is very useful Used (provide read AP request when executing the next AP transaction the result of). This read buffer captures data from the AP, shown as

The result of a previous read, without initiating a new operation.

33.4.6 SW-AP Register

These registers can be accessed when APnDP=1:

There are multiple AP registers, which are addressed in the following combinations:

- Shift value A[3:2]
- Current value of DP SELECT register

Address	A[3:2] value	Note
0x0	00	Reserved, must remain at reset value.
0x4	01	DP CTRL/STAT register. Used for: - Request system or debug power up - Configure transport operations for AP access - Control compare and verify operations - read some status flags (overflow and power-on acknowledgment)
0x8	10	DP SELECT Register: Used to select the currently accessed port and active 4 - word register window. - Bits 31:24: APSEL: Select the current AP (select the current AP) - Bits 23:8: Reserved - Bits 7:4: APBANKSEL: Select the active 4- word register window on the current AP - Bits 3:0: Reserved
0xC	11	DP RDBUFF register: used to obtain the final result after performing a series of operations through the debugger (No need to request new JTAG-DP operations)

33.5 Kernel debugging

Debug the kernel through the kernel debug registers. Debug access to these registers is through the debug access port. It consists of four registers:

Register	Note
DHCSR	32-bit debug stop control and status register This register provides information about the state of the processor, enables the core to enter a debug stop state, and provides processor stepping capabilities.
DCRSR	17-bit debug core register selector registers: This register selects the processor register to be read or written.
DCRDR	32-bit Debug Core Registers Data Registers: This register holds the data read and written between the register and the processor selected by the DCRSR (selector) register data.
DEMCR	32-bit Debug Exception and Watchdog Control Registers: This register provides vector capture and debug monitor control.

These registers are not reset on system reset. They can only be reset by a power-on reset. See Cortex®-M0+ TRM for more details.

In order to put the core into the debug stop state immediately after reset, it is necessary to:

- Enable Debug and Exception Monitoring Control Register Bit 0 (VC_CORRESET)
- Enable Debug Halt Control and Status Register bit 0 (C_DEBUGEN)

33.6 BPU (Breakpoint Unit)

The Cortex®-M0+ BPU implementation provides four breakpoint registers.

33.6.1 BPU function

Processor breakpoint implements PC- based breakpoint functionality.

See the ARMv6-M ARM® and ARM® CoreSight Components Technical Reference Manual for more information on the BPU CoreSight Identification Registers, their addresses and access types.

33.7 DWT (Data Watchpoint)

The Cortex®-M0+ DWT implementation provides two watchpoint register sets.

33.7.1 DWT function

Processor watchpoints implement data address and PC-based watchpoint functionality (i.e. PC sampling registers) and support for comparator address masks as described in ARMv6-M ARM®.

33.7.2 DWT Program Counter Sample Register

Processors implementing the Data Watchpoint Unit also implement the ARMv6-M optional DWT Program Counter Sampling Register (DWT_PCSR). This register allows the debugger to periodically sample the PC without halting the processor. This provides a rough analysis. See ARMv6-M ARM® for more information.

Cortex®-M0+ DWT_PCSR records passing condition codes and instructions and instructions failing condition codes.

33.8 MCU debug group (DBG)

MCU Debug Component helps the debugger provide support for:

- Low power mode
- Timer during breakpoint, clock control of watchdog

33.8.1 Debug support for low power modes

To enter low-power mode, the instruction WFI or WFE must be executed.

The MCU supports several low-power modes that disable the CPU clock or reduce CPU power consumption.

FCLK or HCLK during a debug session. They must remain active as they are required for debug connections during debugging. The MCU incorporates special methods that allow users to debug software in low-power modes.

33.8.2 Debug support for timers, watchdog

During a breakpoint, the behavior of the counters of the timer and watchdog must be selected:

- The counter continues to count while the breakpoint is generated. For example, this is often required when PWM is controlling a motor.
- When a breakpoint is generated, the counter stops counting. This is required when used with a watchdog.

33.9 Debug mode module working state control (DEBUG_ACTIVE)

Reset value 0x00001FFF (this register setting has an effect only in SWD debug mode)

Offset address: 0x4000_2038

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

12	LPTIM1	When debugging, the LpTimer1 counting function configures 1: In the SWD debugging interface, suspend the counting function of LPTimer1 0: In the SWD debugging interface, LPTimer1 counts normally
11	TIM3	When debugging, Timer3 count function configuration 1: In the SWD debugging interface, the Timer3 counting function is suspended 0: In the SWD debugging interface, Timer3 counts normally
10	Reserved	Keep
9	RTC	When debugging, the RTC count function configuration 1: In the SWD debugging interface, suspend the RTC counting function 0: In the SWD debugging interface, the RTC counts normally
8	WDT	When debugging, the WDT count function configures the 1: In the SWD debugging interface, suspend the WDT counting function 0: In the SWD debugging interface, WDT counts normally
7	PCA	When debugging, the PCA counting function configures 1: In the SWD debugging interface, the PCA counting function is suspended 0: In the SWD debugging interface, PCA counts normally
6	TIM6	When debugging, Timer6 counting function configuration 1: In the SWD debugging interface, the Timer counting function is suspended, and the counting value of the counter needs to be initialized to run again after the pause, otherwise the PWM output phase may be wrong. 0: In the SWD debugging interface, the Timer counts normally
5	TIM5	When debugging, Timer5 count function configuration 1: In the SWD debugging interface, the Timer counting function is suspended, and the counting value of the counter needs to be initialized to run again after the pause, otherwise the PWM output phase may be wrong. 0: In the SWD debugging interface, the Timer counts normally
4	TIM4	When debugging, Timer4 count function configuration 1: In the SWD debugging interface, the Timer counting function is suspended, and the counting value of the counter needs to be initialized to run again after the pause, otherwise the PWM output phase may be wrong. 0: In the SWD debugging interface, Timer counts normally
3	LPTIMO	When debugging, LpTimer0 counting function configuration 1: In the SWD debugging interface, suspend the counting function of LPTimer0 0: In the SWD debugging interface, LPTimer0 counts normally
2	TIM2	When debugging, Timer2 counting function configuration 1: In the SWD debugging interface, the Timer counting function is suspended 0: In the SWD debugging interface, the Timer counts normally
1	TIM1	When debugging, the Timer1 count function configures the 1: In the SWD debugging interface, the Timer counting function is suspended 0: In the SWD debugging interface, the Timer counts normally
0	TIMO	When debugging, Timer0 counting function configuration 1: In the SWD debugging interface, the Timer counting function is suspended 0: In the SWD debugging interface, the Timer counts normally

34 Device electronic signature

The electronic signature is stored in the system storage area of the flash memory module and can be read by SWD or CPU. HC32Fxxx / HC32Lxxx microcontrollers with different configurations.

34.1 Product Unique Identifier (UID) Register (80 bits)

Typical application scenarios for unique identifiers:

- Used as a serial number
- UID is used as a security key when used in conjunction with software cryptographic primitives and protocols to increase the security of code in Flash prior to programming the internal Flash
- Activation of the secure bootstrap process, etc.

The 80-bit unique device identifier provides a reference number that is unique to any device and in any context. The user can never change these bits. The 80-bit UID can also be read in different ways like single byte/halfword/word and then concatenated using a custom algorithm.

Base address: 0x0010 0E74

Offset address	Description	UID Bits (80 bits)							
		7	6	5	4	3	2	1	0
0	Lot Number	UID[7:0]							
1		UID[15:8]							
2		UID[23:16]							
3		UID[31:24]							
4		UID[39:32]							
5		UID[47:40]							
6	X Coordinate on the wafer	UID[55:48]							
7	Y Coordinate on the wafer	UID[63:56]							
8	Wafer Number	UID[71:64]							
9	Rev ID	UID[79:72]							

34.2 Product Model Register

0x0010 0C60 ~ 0x0010 0C6F stores the ASCII code of the product model. If the product model is less than 16 bytes, fill it with 0x00.

Example: The product model represented by 484333324C3133364B38544100000000 is HC32L136K8TA.

34.3FLASH capacity register

Base address: 0x0010 0C70

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FlashSize[31:16]															
R															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FlashSize[15:0]															
R															
Bit	Marking	Functional description													
31:0	FlashSize	The capacity of the product's built-in Flash, in bytes 0x00008000 means the Flash capacity is 32K Byte													

34.4RAM capacity register

Base address: 0x0010 0C74

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RamSize[15:0]															
R															
Bit	Marking	Functional description													
31:0	RamSize	The capacity of the product's built-in RAM, in bytes 0x00000800 means the RAM capacity is 2K Byte													

34.5Pin Count Register

Base address: 0x0010 0C7A

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PinCount[15:0]															
R															
15:0	PinCount	The number of product pins, in unit 0x0020 means that the number of product pins is 32													

35 Appendix A SysTick Timer

35.1 Introduction to SysTick Timers

If the OS wants to support multitasking, it needs to perform context switching periodically, so hardware resources such as timers are needed to interrupt program execution. When the timer interrupt is generated, the processor will perform OS task scheduling in exception handling, and will also perform OS maintenance work at the same time. There is a simple timer called SysTick in the Cortex-M0 processor, which is used to generate periodic interrupt requests.

SysTick is a 24-bit timer and counts down. After the count of the timer is reduced to 0, a programmable value will be reloaded, and a SysTick exception (exception number 15) will be generated at the same time. This abnormal event will cause the execution of SysTick exception handling, which is a part of the OS.

For systems that do not require an OS, the SysTick timer can also be used for other purposes, such as timing, timing, or providing an interrupt source for tasks that need to be executed periodically. The generation of SysTick exception is controllable. If the exception is disabled, the SysTick timer can still be used by polling, such as checking the current count value or polling the count flag.

35.2 Set SysTick

Since the reload value and current value of the SysTick timer are undefined at reset, in order to prevent abnormal results, the configuration of SysTick needs to follow a certain process:

Step1: Configure SysTick->CTRL. ENABLE is 0, disable SysTick.

Step2: Configure SysTick->CTRL. CLKSOURCE to select the clock source of SysTick.

Step3: Configure SysTick->LOAD, select the overflow period of SysTick.

Step4: Write any value to SysTick->VAL, clear SysTick->VAL and SysTick->CTRL. COUNTFLAG.

Step5: Configure SysTick->CTRL. TICKINT is 1, enable SysTick interrupt.

Step6: Set SysTick->CTRL. ENABLE to 1 to enable SysTick.

Step7: Read SysTick->CTRL in the interrupt service routine to clear the overflow flag.

Note: Systick overflow period is SysTick->LOAD+1, the configuration example is as follows:

Timer	SysTick->LOAD	Overflow cycle
HCLK 4MHz	3999	1ms
XTL 32.768KHz	327	10.01ms

35.3 SysTick register

Address	Name	CMSIS symbol	Full name
0xE000E010	SYS_CSR	SysTick->CTRL	SysTick Control and Status Register
0xE000E014	SYS_RVR	SysTick->LOAD	SysTick reload register
0xE000E018	SYS_CVR	SysTick->VAL	SysTick current value register
0xE000E01C	SYS_CALIR	SysTick->CALIB	SysTick Calibration Value Register

35.3.1 SysTick Control and Status Register (CTRL)

Bit	Symbol	Functional description	Types of	Reset value
31:17	Reserved	-	-	-
16	COUNTFLAG	SysTick timer overflow flag 1: SysTick timer underflow occurred 0: SysTick timer has not overflowed Reading this register clears the COUNTFLAG flag	RO	0
15:3	Reserved	-	-	-
2	CLKSOURCE	SysTick clock source selection 1: Use the core clock (HCLK) 0: Use reference clock (XTL) Note: When the reference clock is selected as the clock source of SysTick, the XTL clock source and SysCtrl.PERI_CLKEN0.TICK need to be enabled synchronously	RW	0
1	TICKINT	SysTick interrupt enable 1: enable interrupt 0: disable interrupt	RW	0
0	ENABLE	SysTick timer enable 1: enable SysTick 0: disable SysTick	RW	0

35.3.2 SysTick reload register (LOAD)

Bit	Symbol	Functional description	Types of	Reset value
31:24	Reserved	-	-	-
23:0	RELOAD	SysTick timer reload value	RW	Undefined

35.3.3 SysTick Current Value Register (VAL)

Bit	Symbol	Functional description	Types of	Reset value
31:24	Reserved	-	-	-
23:0	CURRENT	Read this register to get the current count value of the SysTick timer Write any value to this register, clear this register and COUNTFLAG	RW	Undefined

35.3.4 SysTick Calibration Value Register (CALIB)

Bit	Symbol	Functional description	Types of	Reset value
31	NOREF	SysTick current count clock flag 1: The current count clock is the core clock 0: The current count clock is external reference clock (XTL)	RO	-
30	SKEW	TENMS Accuracy Indication 1: TENMS value represents roughly 10ms 0: TENMS value represents exactly 10ms	RO	
29:24	Reserved	-	-	
23:0	TENMS	10 millisecond calibration value	RO	-

36 Appendix B Document Conventions

36.1 List of register-related abbreviations

The following abbreviations are used in register descriptions:

RW: Read and write, software can read and write these bits.

RO: Read only, software can only read these bits.

WO: Write only, software can only write to this bit. Reading this bit will return invalid data.

W1: Only write 1, the hardware automatically clears 0, writing 0 is invalid.

ROW1: software reads this bit as 0, writes 1 to clear this bit. Writing a 0 has no effect on the value of this bit.

RW0: Software can read and write this bit, writing 1 is invalid, writing 0 clears.

R1W0: Software reads this bit as 1, and writes 0 to clear this bit. Writing a 1 has no effect on the value of this bit.

RC: Software can read this bit. When this bit is read, it is automatically cleared. Writing "0" has no effect on the value of this bit.

Res, Reserved: Reserved bit, must keep the reset value.

36.2 Glossary

This section provides brief definitions of acronyms and abbreviations used in this document:

Word: 32 -bit data.

Half Word: 16 -bit data.

Byte: 8 -bit data.

IAP (In-Application Programming): IAP means that the microcontroller's Flash can be reprogrammed while the user program is running.

ICP (In-Circuit Programming): ICP means that the Flash of the microcontroller can be programmed using the JTAG protocol, SWD protocol or bootloader when the device is installed on the user application circuit board.

AHB: Advanced High Performance Bus.

APB: Low-speed peripheral bus.

DMA: Direct Memory Access.

TIM: Timer.

Version Revision History

Version Number	Revision Date	Modify the content
Rev1.00	2019/11/20	The first draft is released.
Rev1.10	2019/12/31	Update the following information: ①Add QFN32 package; ②Typical application circuit diagram; ③Device electronic signature; ④Appendix A SysTick timer; ⑤Diagrams and precautions for high-speed external clock XTH and low-speed external clock XTL; ⑥ General working conditions description; ⑦System control register 1 (SYSCTRL1) adds notices; ⑧Using a temperature sensor to measure the ambient temperature; ⑨The description of the DMA controller (DMAC) and cyclic redundancy check (CRC) chapters; ⑩The 0 bit of the I2C configuration register (I2Cx CR).
Rev1.20	2020/04/10	Update the following information: ① Pin function description; ② 29.7.2.17 and 29.7.2.24 add notices; ③ 7.5.1 and 7.5.2 Step8; ④ package size QFN32; ⑤ 3.2.7 and 3.2.8 add Step; ⑥Add AVCC/3 precision in ADC features; ⑦Change 44/45/47/48pin of HC32L073KATA; ⑧Change 32/33/35/36pin of HC32L073JATA.
Rev1.30	2020/05/29	Update the following information: ① 11.3.2 deleted the note; ② Corrected typos in external low-speed clock input; ③ Added LCD controller; ④ RCL oscillator accuracy in internal RCL oscillator; ⑤ Product features Added low-power timer description in ultra-low-power MCU; ⑥Added Step2 and Step3 in 7.5.
Rev1.40	2020/06/30	Update the following information: ①Add I2S information in the pin function description; ②LPTIM is corrected to LPTIM0, and LPTIMx_ETR is corrected to LPTIMx_EXT; ③Unified pin function names and unified register names; ④Update 21.3.1.6 and 22.3.2.6 descriptions.
Rev1.50	2020/07/31	Update the following information: ①Input characteristics - V _{IH} value and value in ports PA, PB, PC, PD, PE, PF; ②Add TIM timer characteristics and communication interface section; ③EFT characteristic level; ④Adjust 29.7.1 and 29.7.2 Registers.
Rev1.60	2020/09/30	Update the following information: ①Functional block diagram in function module; ②Add SPI feature and I2S feature; ③11.8.4, 11.8.14 and 35.4.2 update typos; ④Clock system description; ⑤V _{IL} and V _{IH} of RESETB pin characteristics; ⑥Add input Features - USB_DP, USB_DM; ⑦ bit3 of 28.7.3.
Rev1.61	2020/12/31	Delete product features, pin configuration, packaging information, etc. (please refer to the latest data sheet for related information), and revise the statement.
Rev1.62	2021/09/17	Replace with high-resolution vector graphics.
Rev1.63	2022/03/09	The company logo is updated.
Rev1.64	2022/08/13	Update the following information: ①Chapter "I2C bus ", I2C operation process errata; ②Chapter " External high-speed crystal oscillator clock XTH", add a description that recommends using an active crystal oscillator; ③Chapter " Port digital multiplexing function ", delete the PF01 function of TIM4_CHB Mapping; ④Chapter " Cycle Interval Response ", add the description of the initialization method of this function and precautions; ⑤Chapter " Baud Rate Setting ", add the description of sampling points; ⑥Chapter " Controller Local Area Network ", add the precautions for using CAN.
Rev1.65	2023/06/21	Update the following information: ①"Pulse Width Measurement PWC register Description" section, add the function description not opened to the control register (TIMx_CR0).
Rev1.70	2024/05/23	Update the following information: ①3.5.2 Change the notes of the EXTL_EN and EXTH_EN function description of the SYSCTRL1 register;

Version Number	Revision Date	Modify the content
		②7.5 Update the programming example operation steps; ③Add PLL to the monitored clock source in 9.3.2.2 Clock Monitoring Hardware Structure; ④Add notes in 15.2.3.2 PCA 16-bit PWM function; ⑤Change PC5 to PC15 in 16.3.30 TIMx_PTBS and 16.3.33 TIMx_PTBK; ⑥Update the BEIF function description of 26.5.9 CAN_ERRINT register; ⑦1.2V related content is removed from the analog-to-Digital Converter (ADC) section; ⑧The reference voltage of 1.2V and the on-chip BGR output is removed from the Analog Voltage Comparator (VC) section.
Rev1.71	2025/01/14	Update the following information: ①3.5.2 Change the notes in the function description of EXTL_EN and EXTH_EN of SYSCTRL1 register.
Rev1.72	2025/03/28	Update the following information: ①Delete the description of the maximum communication rate between master and slave in Section 8.2 Main Features of SPI.
